P is the 16th letter of our alphabet. It was also a letter in the alphabet used by the Semites, who once lived in Syria and Palestine. They named it *pe,* their word for *mouth,* and adapted an Egyptian *hieroglyphic* (picture symbol) meaning *mouth* to represent it. The ancient Greeks took the letter for their alphabet and called it *pi.* When the Romans adopted the Greek alphabet, they developed the letter form that we use today. See **Alphabet.**

Uses. *P* or *p* is about the 18th most frequently used letter in books, newspapers, and other printed material in English. In chemistry, *P* stands for *phosphorus. P* is used as an abbreviation for *post,* as in *P.S.* for *postscript.* Post comes from the Latin word for *after,* and we also use it in *p.m.,* or *post meridiem,* for afternoon. In bibliographies, *p* stands for *page;* in money, *p* stands for *penny* and for *peso,* a unit of currency in Spanish-speaking countries. In grammar, *p* represents *past* and *participle.* In music, it stands for *piano,* an Italian word that means *softly.*

Pronunciation. In English, a person pronounces *p* by closing the lips and the velum, or soft palate, and temporarily stopping the breath passage. The vocal cords are apart, and do not vibrate. The typical sound of *p* occurs in such words as *pie* and *pen.* The combination *ph* is often sounded as *f* in such words as *physics* and *photograph. P* is silent in such words as *pneumonia* and *raspberry.* The letter has always had much the same sound. See **Pronunciation.** Marianne Cooley

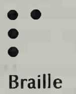
Development of the letter P

The ancient Egyptians used this symbol for *mouth* about 3000 B.C.

The Semites, about 1500 B.C., adapted the Egyptian symbol. They used it for the letter *pe,* their word for *mouth.*

The Phoenicians used a rounded, hook-shaped letter about 1000 B.C.

The Greeks squared the hook and added it to their alphabet about 600 B.C. They named the letter *pi.*



The Romans gave the P its present shape about A.D. 114.

The small letter p appeared during the A.D. 600's. By about 1500, the letter had developed its present form.

Computer letters have special shapes. Computers can "read" these letters either optically or by means of the magnetic ink with which the letters may be printed.

PAC. See Political action committee.

Paca, *PAH kuh* or *PAK uh,* is a large rodent found in the tropics of North and South America. Pacas measure 24 ½ to 32 ½ inches (62 to 83 centimeters) long. Most pacas weigh 14 to 22 pounds (6.3 to 10 kilograms).

Pacas have a small, thick head; stout body; short, slender legs; and short tail. There are five long toes on each back foot and four on each front foot. Pacas are covered with rough, brownish or black hair. Four rows of white spots line each side of their body. Pacas have unusually large cheek pouches. The pouches form roomy chambers that help the animal make sounds.

Pacas are found from central Mexico south to Paraguay, and in the Andes Mountains of Venezuela, Colombia, and Ecuador. They live in forests, usually near rivers. Pacas are good swimmers and often escape from enemies by water. Most pacas live alone in burrows, caves, woodpiles, stumps, or rocks. Most females produce two litters a year of one or two young.

The paca is a large rodent that lives in forests.

Pacas come out for food only at night. They eat plants, roots, seeds, and tropical fruit. Pacas also sometimes eat such crops as sugar cane, corn, and yams, and are often hunted in areas where these crops grow. Hunters also kill pacas for their tasty flesh, which is eaten. Wild dogs and ocelots also prey on pacas. Charles A. Long

Scientific classification. Pacas belong to the family Agoutidae. The scientific names for the two most common species are *Agouti paca* and *A. taczanowski.*

Paca, *PAY kuh,* **William** (1740-1799), a Maryland signer of the Declaration of Independence, took part in many American political movements from 1771 until his death. He served in the Continental Congress from 1774 to 1779, and was governor of Maryland from 1782 to 1785. President George Washington appointed him judge of the Court for Maryland in 1789, a post he held until his death.

Paca was born on Oct. 31, 1740, near Abingdon, Maryland. He attended what is now the University of Pennsylvania and studied law at Annapolis, Maryland, and in London. Gary D. Hermalyn

Pachomius, *puh KOH mee uhs,* **Saint** (290?-346), a Christian monk from Egypt, founded the first Christian religious communities called *monasteries.* He organized the first monastery in 320. He eventually established nine monasteries for men as well as two for women.

Pachomius's monasteries were groups of connected buildings walled off from the outside world where monks and nuns lived under militarylike discipline. Pachomius emphasized manual labor, ascetic practices, common prayer, and strict obedience to the monastery's leaders. In addition, he developed regulations, called a *rule,* to meet the economic and spiritual needs of his monastic communities. Pachomius's rule became the model for all later monastic rules, notably those prepared by Saint Basil and Saint Benedict. In 404, Saint Jerome translated Pachomius's rule into Latin. In this form, it significantly influenced the development of monasticism in the West.

Pachomius was born near Isna, Egypt. He converted to Christianity about 313 and became a hermit. His feast day is May 14. Richard R. Ring

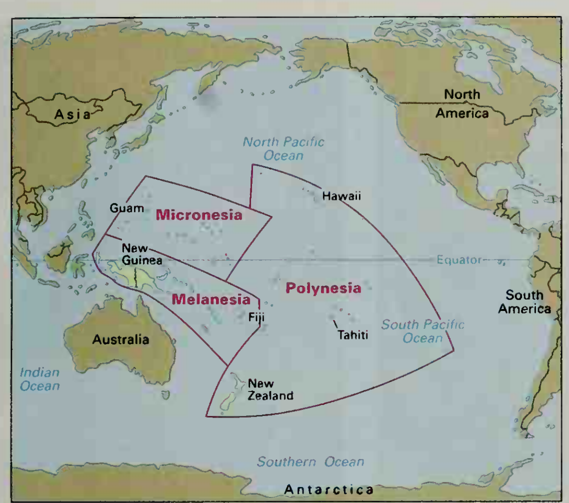
Pachycephalosaurus, *PAK uh SEHF uh luh SAWR uhs,* was a plant-eating dinosaur that had a remarkably thick skull. The name *Pachycephalosaurus* comes from Greek words meaning *thick, head,* and *lizard.*

Pachycephalosaurus possessed a bulky body with short forelimbs and long legs. It probably weighed over 1 ton (0.9 metric ton) and measured 13 to 26 feet (4 to 8 meters) in length. The dinosaur most likely traveled on its hind legs. When moving, *Pachycephalosaurus* may have carried its body parallel to the ground. A network of bony tendons held aloft its heavy, rigid tail.

Pachycephalosaurus's thick head was domed over the braincase. The top of its skull measured up to 10 inches (4 centimeters) thick, and bony knobs covered portions of the skull. The animal may have used its thick dome in butting contests for mates or territory. *Pachycephalosaurus* also had a narrow snout topped by short spikes, possibly for digging up vegetation. Its small, ridged teeth were not strong, and the animal probably ate fruits, leaves, and seeds. A keen sense of smell and large eyes helped it detect approaching predators.



Pachycephalosaurus lived about 68 million to 65 million years ago, during the last part of the Cretaceous Period. Scientists have found the dinosaur's remains in western North America. David B. Weishampel

Pachyderm, *PAK uh durm,* is one of the *pachydermata,* a zoological classification that has been abandoned. This group included such noncud-chewing, hoofed mammals as the elephant and rhinoceros. See also **Elephant** (Skin and hair). Hugh H. Genoways

Pacific Islands, also called Oceania, is the name given to a group of many thousands of islands scattered across the Pacific Ocean. No one knows exactly how many islands are in the Pacific. Geographers estimate that there are from 20,000 to more than 30,000. Some islands cover thousands of square miles or square kilometers. But others are no more than tiny piles of rock or sand that barely rise above the water.

Some islands in the Pacific do not belong to Oceania. Islands near the mainland of Asia, such as those that make up the nations of Indonesia, Japan, and the Philippines, are considered part of Asia. Islands near North America and South America, such as the Aleutians and the Galapagos, are grouped with those continents. Australia is itself a continent and so is not considered part

The Pacific Islands can be divided into three main areas: (1) Melanesia, meaning *black islands;* (2) Micronesia, meaning *small islands;* and (3) Polynesia, meaning *many islands.*

of Oceania. These areas are part of what is called the Pacific Rim.

Although some islands of Oceania are large, all of them together cover less land than does the state of Alaska. New Guinea is the largest island in the group and the second largest island in the world, after Greenland. New Zealand's two main islands are the second and third largest islands in Oceania. Together with New Guinea, they make up more than four-fifths of the total land area of the Pacific Islands.

Oceania can be divided into three main areas: (1) Melanesia, (2) Micronesia, and (3) Polynesia. These areas are based on the geography of the islands and on the culture and ethnic background of the native peoples.

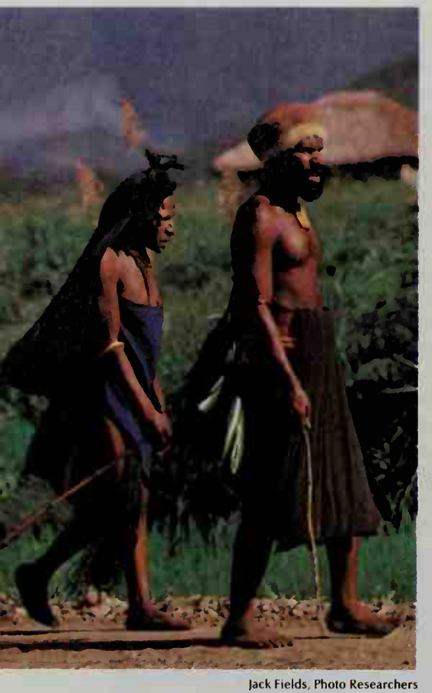
Melanesia means *black islands.* Its name is derived from the word *melanin,* which is the blackish or brownish pigment produced in the skin. The Melanesian people have large amounts of melanin in their skin, which makes their skin very dark. Melanesia includes New Guinea, the Solomon Islands, New Caledonia, and Vanuatu. Fiji is considered part of Melanesia because of its location. But its culture is much more like that of Polynesia. The Melanesian islands lie south of the equator.

Micronesia means *tiny islands.* These islands lie north of Melanesia, and most of them also lie north of the equator. More than 2,000 islands make up Micronesia. Most of them are low-lying coral islands. Micronesia includes Guam, the Caroline Islands, the Mariana Islands, the Marshall Islands, the Gilbert Islands, and the single island of Nauru.

Polynesia means *many islands.* It occupies the largest area in the South Pacific. There are long distances between its island groups. Polynesia stretches from Midway Island in the north to New Zealand, 5,000 miles (8,000 kilometers) to the south. The easternmost island in Polynesia, Easter Island, lies more than 4,000 miles (6,400 kilometers) east of New Zealand.

The land and climate differ greatly throughout the Pacific Islands. Many of the islands, especially those in Polynesia, are famous for their sparkling white beaches, gentle ocean breezes, and swaying palm trees. Some other islands, especially in Melanesia, have thick jungles and tall mountain peaks. Many lowland areas in these islands are steaming hot, but the tallest mountain peaks are covered with snow throughout the year.

About 15 million people live in the Pacific Islands. Only a few islands or island groups, such as Fiji, Hawaii, New Guinea, and New Zealand, have large numbers of people. Many islands have fewer than a hundred people, and others have none at all.



The first Pacific islanders came from Southeast Asia several thousand years ago. Their earliest settlements were in Melanesia and Micronesia. Most of Polynesia was settled later.

Over a period of thousands of years, a variety of cultures developed in the Pacific Islands. This variety resulted in part from the varied environments on the different islands. However, most of the islanders traditionally lived in villages and fished or farmed. They knew nothing of what went on in the rest of the world, and the rest of the world knew nothing of the islands. Then in the 1500's, the first Europeans arrived in the Pacific. By the late 1800's, several European countries and the United States had taken control of most of Oceania.

Population groups. Some scientists divide the people of the Pacific Islands into three population groups—Melanesian, Micronesian, and Polynesian. Melanesians, shown in the photograph at the left, have the darkest skin. Micronesians, *center,* have a somewhat lighter skin. Polynesians, *right,* are the tallest and lightest skinned.

Americans and Europeans brought their own ways of life to the islands. As a result, the islands have two ways of life today. There is the new way, brought by Americans and Europeans, and the old way, handed down for hundreds or thousands of years. Many islands now have busy, rapidly growing towns and cities much like those in North America and Europe. But most people still live in villages, and many of them follow the same way of life their ancestors did.

New Zealand and Hawaii differ from the rest of Oceania in many ways. New Zealand is an independent, highly developed nation and has a modern economy. Most of its people have a European background. Hawaii is a state of the United States and, like New Zealand, has a modern economy (see **Hawaii; New Zealand**).

This article deals mainly with the other islands of the Pacific. At one time, most of them were ruled by other countries. But many of the people on these islands felt that the ruling countries had taken much more from the islands than they had given in return. Beginning in the early 1960's, a growing number of islanders demanded the freedom to govern themselves. As a result, today most islands or island groups are independent or have some form of self-government.

People

The first settlers in the Pacific Islands probably came from Southeast Asia thousands of years ago. They reached the islands by means of rafts or dugouts and followed land bridges whenever possible. Over many centuries, most of the islands of the Pacific became settled. But large expanses of ocean separated the people in one part of the Pacific from those in another. As a result, people in distant island groups had little or no contact with one another.

During the 1700's and 1800's, European explorers visited most of the Pacific Islands. They noted that people in Melanesia, Micronesia, and Polynesia differed from one another in appearance. The islanders also had different languages, religions, and customs.

Some scientists divide the people of the Pacific Islands into three main groups—Melanesian, Micronesian, and Polynesian. However, other scientists suggest only two basic divisions of the islanders—Melanesian and Micronesian/Polynesian.

The population groups are not clearly divided among the three geographic and cultural areas of the Pacific Islands. For example, groups of people with Polynesian features live in parts of New Guinea, which is deep in Melanesia. Furthermore, people from each of the areas have migrated to the other regions. Asians and Europeans have also migrated to the islands and married islanders. Their children have mixed physical features. Nevertheless, there are still noticeable physical differences among the people in the three areas.

Melanesians are the shortest of the peoples of the Pacific Islands. Many resemble black Africans. In addition to their dark skin, most have black, woolly hair. Some Melanesians, called *Negritos,* are like the Pygmies (see **Negritos; Pygmies**).

Micronesians are somewhat taller and have somewhat lighter skin than the Melanesians. Most Micronesians have wavy or woolly hair. Those who live closest to Asia have certain Asian characteristics, such as high

cheekbones and straight hair. The people of the Yap Islands and some of the people of the Palau Islands are quite dark and look like the Melanesians.

Polynesians are the tallest and have the lightest skin of the Pacific peoples. They have straight to wavy hair. Some Polynesians—especially those of the island groups of Samoa, Tonga, and Hawaii—are robust, large-boned people. Marriages between islanders and Asian or European settlers have been more common in Polynesia than in the other two culture areas. As a result, many Polynesians have mixed Asian, European, and Polynesian physical traits.

Other peoples make up only a small part of the total population of the Pacific Islands. Only Hawaii and New Zealand have a majority of people who are not native to the islands. Hawaii has many American and Japanese settlers. Most New Zealanders are descendants of British settlers.

Smaller groups of Asians and Europeans live in other parts of the Pacific Islands. More than a third of the people of New Caledonia are of European or part European descent. Tahiti and some other islands in French Polynesia have a number of French and Chinese settlers. Smaller numbers of Europeans and Chinese live in Fiji and New Guinea. Wherever they have settled, Americans, Asians, and Europeans have had great influence on the lives of the islanders. Some island leaders feel that these outside influences have been too great and that the islanders have given up too many of their own traditions and customs.

Languages. About 1,200 of the world's 3,000 languages are spoken in the Pacific Islands. Melanesia has the greatest number of languages. More than 740 languages are spoken in Papua New Guinea alone. Micronesia has about 13 major languages. Polynesia has about 20 languages, all of which are closely related.

English is the most widely used language in the Pacific Islands. It is the official language of Hawaii and of several independent nations, including Fiji, New Zealand, Samoa, and Tonga. English is also the official language of island territories controlled by Australia, Britain, New Zealand, and the United States. But many of the people of these territories speak only their island language.

Some people who live on islands of western Micronesia speak Japanese, which they learned when Japan controlled the islands from 1920 to 1945. French is the official language of the territories controlled by France, but the islanders also speak their own languages.

A language called *Pidgin English* or *Neo-Melanesian* has developed on all the main islands of Melanesia except Fiji and New Caledonia. Pidgin English consists mainly of words from English and the island languages. This language gives the people of Melanesia, who speak many languages, a means of communicating with one another.

Religions. Christianity has been the main religion in Oceania since the late 1800's. Before then, the islands had a number of religions, all based on a belief in numerous gods or spirits. Most religions had a complicated mythology made up of stories about the creation of the earth and the relationships between the gods and people (see **Mythology** [Mythology of the Pacific Islands]).

Today, island religions survive mainly in Melanesia, particularly in New Guinea, the Solomon Islands, and Vanuatu. But even in areas where most of the people are Christians, many of the islanders still believe in magic and witchcraft.

A kind of religion called a *cargo cult* exists in parts of Melanesia. Members of a cargo cult believe that the gods intend them to have a share of the goods that Westerners enjoy. The cargo cult's leaders promise that one day a giant cargo ship or plane will arrive containing the islanders' share of Western goods.

In a few parts of the Pacific Islands, the people once practiced *cannibalism* (the eating of human flesh). Some people considered it a religious ceremony. They believed that by eating a dead person's flesh, they took on that person's good qualities. Cannibalism no longer exists in the Pacific Islands except in New Guinea, where it occasionally occurs.

Ways of life

Most Pacific islanders live in small farming or fishing villages. Many of them live in the same kinds of houses, eat the same kinds of food, and wear the same kinds of clothing their ancestors did. But these traditional ways of life are changing rapidly as more and more people adopt the customs of Western countries.

Villages. Many Pacific islanders have left their villages to work in the towns and cities, but the village remains the basic community of the islands. The smallest villages have only a few people, and the largest have several hundred. All the families of a village feel strong ties to one another even though they may not be related. Such *kinship groups* play an important part in the lives of most Pacific islanders. In Polynesia, the people of some entire islands and groups of islands feel bound by ties of kinship.

In most villages, each family has its own house or cluster of houses. A household may include grandparents, aunts, uncles, and cousins. Most houses have a wooden framework, with walls and roof made of thatch. They have a round, oval, square, or oblong shape. In the hot coastal areas of New Guinea, many people build their homes on stilts, which makes the houses cooler and protects them from moisture on the ground. In the cool highlands of New Guinea, most of the houses are low and circular, with tightly fitted walls of wood and thatch to help conserve heat on chilly nights.

Chiefs play an important part in the affairs of many villages. A village chief is expected to advise and lead the people, show hospitality to visitors, and uphold the good name of the community. On most Pacific Islands, the chief inherits the office. In Polynesia and on Fiji, the office of chief passes from father to son. In most parts of Micronesia, a chief is succeeded by the oldest son of the chief's oldest sister. In Melanesia, a village chief earns the office by achievement rather than by birth.

Towns and cities. Oceania has few towns and cities, but they are growing rapidly. Hawaii and New Zealand have the only large cities in the islands. The largest city outside Hawaii and New Zealand is Port Moresby, Papua New Guinea. Other small cities or large towns include Apia in Samoa, Noumea in New Caledonia, Papeete in French Polynesia, and Suva in Fiji. Most towns and cities in Oceania have an elected governing body.

Emil Muench from Carl Östman

Traditional ways of life are followed by many Pacific Islanders, especially villagers who earn little or no money. At this village market in New Guinea, many of the people trade one kind of farm product for another, just as their ancestors did.

Houses in Pacific Island towns and cities look much like those in Western countries and are made of such materials as wood, concrete block, and brick. The rapid growth of towns and cities has created a housing shortage in some areas. As a result, shantytowns have sprung up on the outskirts of the fastest-growing towns. Some island governments have started programs to build modern, inexpensive houses.

Food. Traditionally, the people of the Pacific Islands have depended largely on fish and native plants for food. In shallow water, people catch crabs, lobsters, shrimps, and turtles. Farther out at sea, they catch bonito and tuna. On many islands, the people eat the fruit of breadfruit and pandanus trees and the meat of coconuts from the coconut palm. The people of New Guinea make flour from the starchy *pith* (soft center) of the sago palm. They use the flour to make small cakes and biscuits. Many islanders have vegetable gardens in which they grow sweet potatoes and *taro,* a plant with a starchy underground stem. Many people also raise bananas and some plants introduced from other parts of the world, such as corn, pineapples, rice, and tomatoes. Some farmers also have chickens and pigs.

Many islanders cook their food in ground ovens. A common type of ground oven consists of a shallow pit lined with heated stones. The food is placed on the stones and covered with a layer of leaves. The pit is then filled with earth to hold in the heat.

Although many islanders still eat the traditional foods, canned foods from Western countries have become so popular on some islands that many people eat almost nothing else. As a result, malnutrition is a problem in many cities and towns. Local health agencies try to persuade the people to balance their diets with fresh fruits, vegetables, and meats.

Clothing. Many people in the Pacific Islands, especially in the towns and cities, wear Western-style clothing. But some villagers wear traditional dress. In Polynesia and Fiji, the men often wear a cloth skirt called a *lava-lava* or *sulu.* Some women in Fiji, Hawaii, and the Samoa Islands wear long, loose-fitting cotton garments called *muumuus.* In Fiji, the Samoa Islands, and Tonga, women also make skirts of *tapa cloth.* They make tapa cloth by stripping the inner bark from paper mulberry trees, soaking it, and then beating it with wooden clubs. On a number of islands—especially the Gilbert Islands, New Guinea, and the Solomon Islands—both men and women sometimes wear grass skirts. A few mountain tribes in New Guinea, the Solomons, and Vanuatu wear only brief coverings of bark or leaves around their waists. In the cool New Guinea highlands, some of the people keep warm by greasing their naked bodies with pig fat.

Arts and crafts. Many islanders, especially in the villages, are skilled artists and craftworkers. On some islands, the people use the leaves and fibers of native plants, such as palm and pandanus trees, to weave baskets and mats, which they decorate with colorful designs. Some islanders use native woods to carve masks, cooking utensils, and other objects. On a few islands, people make pottery. The islanders sell some of their handicrafts to tourists and export companies. See **Sculpture** (Pacific Islands sculpture) for a description and pictures of the colorful sculpture of the Pacific area.

Recreation. On most islands of the Pacific, the villagers gather for traditional feasting, dancing, and singing on such occasions as births and marriages. Dancing is a major part of village festivities. The dancers often wear masks, feathers, flowers, sea shells, or other colorful ornaments. Polynesian dancing is especially lively. The Tahitian *tamure* and the Hawaiian *hula* are popular Polynesian dances. On some Polynesian islands and on

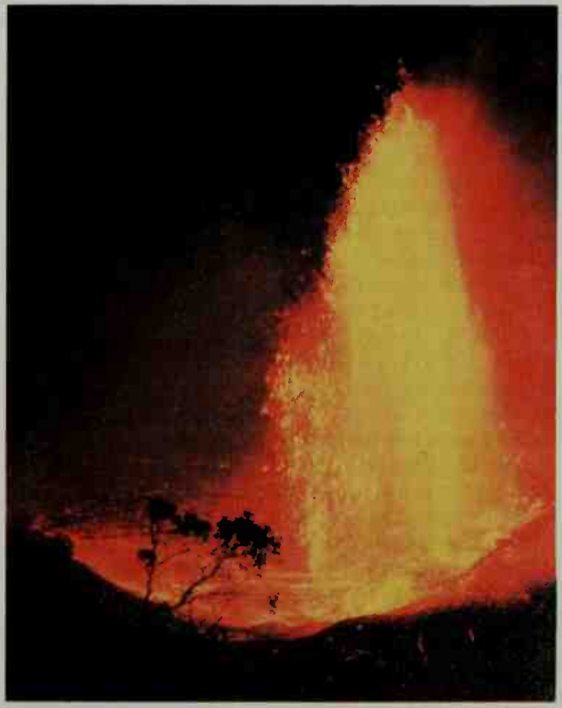
New ways of life have come mainly from the West. These Fiji islanders are playing rugby football, a British game. Many Pacific islanders—especially in the towns and cities—have given up their native customs and adopted Western ways.

Fiji, important festivals include the ceremonial drinking of *kava,* a drink made from the roots of the native kava plant. Many islanders enjoy playing games introduced from Western countries, such as volleyball and rugby football.

Education. All the populated islands of Oceania have elementary schools, and many also have high schools. Christian missionaries started the first schools in the Pacific and continue to operate many of them today. Most islands could not afford to run schools without the missionaries' help. But some island governments are able to assist the mission schools financially.



Many island children do not continue their education beyond elementary school. Relatively few young people finish high school and go on to colleges or universities. Hawaii and New Zealand have the only large universities in the Pacific Islands. Smaller universities are located in Fiji, Guam, and Papua New Guinea. Some islands have small colleges that specialize in agriculture, medicine, or theology.

The land and climate

The islands of the Pacific can be divided into two main types: (1) high islands and (2) low islands.

The high islands are made up largely of hills and rugged mountains. Some of the mountains rise high above sea level, and many are active volcanoes. The high islands also have frequent, sometimes severe, earthquakes. The largest islands of the Pacific—New Britain, New Caledonia, New Guinea, and New Zealand—are high islands. The high islands also include the main islands of such groups as Fiji, Hawaii, the Marianas, Samoa, the Solomons, and Vanuatu.

The low islands consist of *coral reefs,* which are formed by the skeletons of millions of tiny sea animals (see **Coral**). Thousands of these islands are scattered throughout the Pacific. Most of them are smaller than the high islands and rise only a few feet or a meter above sea level. Earthquakes in the Pacific sometimes create large, destructive ocean waves called *tsunamis*

Two main types of islands are found in the Pacific. *High islands* are mountainous and volcanic. *Low,* or *coral, islands* are formed by skeletons of tiny sea animals. The island in the background—Bora Bora—is a high island surrounded by small coral islands like the one in the foreground.

that flood the lowest of these islands.

The majority of the low islands are *atolls.* An atoll is a coral reef—or a number of small reefs called *motus*—surrounding a large lagoon. The low islands include all the islands in the Gilbert, Marshall, Phoenix, Tuamotu, and Tuvalu groups, as well as many individual islands in other groups. Movements within the earth have lifted some atolls higher than others. Such *raised atolls* include Nauru and Niue. Coral reefs or atolls also lie off the shores of most high islands.

Climate. Almost all the islands of the Pacific lie in the tropics and so are warm the year around. On most islands, the temperature seldom falls below 70 °F (21 °C) or rises above 80 °F (27 °C). But mountain areas in New Guinea and a few other high islands are somewhat cooler. The tallest mountains in New Guinea and New Zealand are snow covered the year around.

Rainfall varies greatly throughout Oceania. Some islands, especially the low islands, may have only a few inches or centimeters of rain a year. Other islands, especially the Carolines and the high islands in western Melanesia, often have more than 150 inches (381 centimeters) a year. Most islands have a wet season and a dry season. In Melanesia and Polynesia, the wet season lasts from December to March and the dry season from April to November. In Micronesia, the wet season lasts from May to December and the dry season from January to April.

Typhoons often strike islands in the Pacific. They bring violent winds and heavy rains, which sometimes cause great loss of life and enormous property damage. In Micronesia, typhoons may strike at any time, but they occur most frequently from July to October. Most South Pacific typhoons occur from January to March.

Economy

Hawaii, New Zealand, and Nauru have well-developed economies. Hawaii's economy is based largely on U.S. government employment and on tourism. New Zealand has thriving agricultural and manufacturing industries. On these islands, most workers are wage earners. The people of Nauru receive most of their income from mining operations. But on the other Pacific Islands, many people earn little or no money. Most of them are villagers who raise their own food, build their own houses, and make their own clothing. They may earn a small income by raising coconuts, bananas, or sugar cane to sell to export companies. Throughout the Pacific Islands, a growing number of villagers are moving to the towns and cities to work for wages.

Natural resources. On many of the low islands, the soil is too poor and the rainfall too light for plants to grow well. Only grass and small shrubs grow on these islands. Low islands with heavier rainfall have coconut palms and pandanus trees. Many of the high islands have fairly fertile soil and plentiful rainfall. Unusual flow-

ers and trees grow on these islands. New Guinea, the Solomon Islands, and Vanuatu are covered with thick jungles and steaming forests.

The islands' few native animals include birds, land crabs, lizards, and rats. Albatrosses, terns, and other birds are the most common animals. New Guinea and a few of the nearby islands have crocodiles and snakes. These islands also have kangaroos and other *marsupials* (mammals that give birth to extremely undeveloped young).

The islands have few mineral resources, except for valuable deposits of nickel on the island of New Caledonia and copper, gold, and oil on the island of New Guinea. New Caledonia also has some chromium and iron, and Fiji has small deposits of gold and manganese. Nauru has deposits of phosphate, which is used to make fertilizer.

Agriculture is the main industry of Oceania, and *copra* (the dried meat of the coconut) is the most important agricultural product. Factories crush copra to produce coconut oil, which is used to make such products as margarine and soap. Many countries import coconut oil or copra from the Pacific Islands. Tonga, Samoa, Fiji, and the Cook Islands also grow bananas for export. The production and export of sugar is the main industry in Fiji. New Guinea farmers grow cocoa and coffee for sale overseas.

At one time, Europeans owned much of the farmland in the Pacific Islands. Today, many islanders have their own farms. In some villages, the farmland belongs to the entire community.

Mining and manufacturing. Many of the islands are trying to develop other industries in addition to agriculture. Islands with mineral deposits, such as Fiji and New Caledonia, are expanding their mining industries. Phosphate mining is important on Nauru, but phosphate deposits are being used up rapidly.

In larger towns of the Pacific Islands, mills and factories produce such goods as coconut oil, soap, and sugar. The Solomon Islands, Papua New Guinea, Samoa, and some other forested islands use sawmills to process native timbers.

The tourist industry in the Pacific Islands has grown tremendously since the beginning of jet airplane travel in the 1950's. As more and more tourists come to the islands, more airports, hotels, highways, shops, and restaurants will have to be built. Islands that actively encourage tourism, such as the Cook Islands, Fiji, and Tahiti, are working to construct these facilities. However, some islanders fear that further growth of the tourist industry will destroy the natural charm and traditional way of life of the Pacific. In some island groups, attempts have been made to control the development of the tourist industry.

Transportation. Canoes have long been the traditional means of transportation throughout the Pacific Islands. Villagers use them for fishing and for traveling short distances. To make longer voyages, they use canoes equipped with sails or outboard motors.

Many islanders depend on ships and airplanes for transportation. Ships of all sizes connect the major ports, and airplanes deliver food and other supplies to the islands. Fiji, New Guinea, and other islands have their own commercial airlines, which carry both passengers and cargo.

None of the islands has a well-developed highway system. But in the cities and large towns, many people own automobiles, and traffic jams occur during rush hours just as they do in cities elsewhere.

History

The first settlers. Most scholars believe the first settlers in the Pacific Islands came from Southeast Asia thousands of years ago. They probably reached the Pacific by way of Indonesia and then traveled to islands in Melanesia. They followed land bridges when possible and made parts of their journey by water, using rafts or dugouts. Some may have sailed northward to Micronesia. Over hundreds of years, settlements were set up on the main islands of Melanesia and Micronesia.

Most of the islands of Polynesia were settled later than those of Melanesia and Micronesia. Many Polynesian islands are farther apart than islands in Melanesia and Micronesia and so are harder to reach by boat. The first settlers of Polynesia were probably groups of seafaring people from eastern Melanesia or Micronesia. Some of these groups may have set out in search of new homes. Other groups may have been blown off course by violent storms. But in time, groups such as these established settlements on all the main Polynesian islands.

Discovery by Europeans. In 1513, the Spanish explorer Vasco Núñez de Balboa became the first European to sight the eastern Pacific. He saw it from Panama. In 1520, the Portuguese explorer Ferdinand Magellan began to sail westward across the Pacific. In 1521, he reached Guam. After this voyage, many Europeans searched the Pacific for other islands. The Caroline, Marquesas, Solomon, and Tuvalu island groups were visited by Europeans during this period. A Dutch explorer, Abel Janszoon Tasman, arrived in New Zealand in 1642. The greatest Pacific explorer of the 1700's was Captain James Cook of the British Royal Navy. Between 1768 and 1779, he located and accurately mapped many islands in the Pacific, including Hawaii and New Caledonia.

Missionaries, traders, and settlers. Cook's discoveries encouraged Protestants and Roman Catholics to

establish missions throughout Oceania. As a result, many islanders became Christians during the 1800's. Many missionaries introduced genuine improvements to the islands, but others concentrated largely on doing away with native customs and traditions. At the same time, American and European traders searched the Pacific for coconut oil, sandalwood, and other products. Ships from many countries came to hunt whales. Some traders and whalers treated the islanders badly and were badly treated in return. Slave traders called *blackbirders* took shiploads of islanders to work on plantations in Australia and South America.

European settlers also began to arrive in the islands. Wealthy Europeans started coconut, coffee, pineapple, and sugar plantations. But the new settlers also included many criminals and drifters, and lawlessness became a problem. Europeans also brought diseases against which the islanders had no resistance. On some islands, epidemics wiped out most of the population.

Colonial rule. By the late 1800's, the United Kingdom (U.K.), France, Germany, Spain, and the United States were competing to control Pacific islands. After Spain's defeat in the Spanish-American War of 1898, Germany and the United States took over Spain's possessions in Micronesia. By the early 1900's, Germany also held parts of Nauru, New Guinea, and Samoa, and the United States controlled Hawaii and the rest of the Samoa Islands. France controlled New Caledonia and French Polynesia and shared control of the New Hebrides (now Vanuatu) with the U.K. The British held Fiji, Papua, Tonga, the southern Solomons, and the Gilbert and Ellice islands. By 1910, Australia and New Zealand had won independence from the U.K. After Germany's defeat in World War I (1914-1918), Japan took control of Germany's possessions in Micronesia, New Zealand took over German Samoa, and Australia got control of northeastern New Guinea. Through all these changes of rule, the islanders had little or no voice in the government.

World War II (1939-1945). Japan increased its power in the Pacific after World War I. In December 1941, Japanese bombers attacked the U.S. naval base at Pearl Harbor, Hawaii, marking the beginning of World War II in the Pacific. By mid-1942, Japanese troops had captured islands as far east as the Gilberts and as far south as the Solomons. The United States and its allies then began the difficult job of driving the Japanese off these islands. Bloody battles were fought at Tarawa and on Guadalcanal, Iwo Jima, and other islands. In September 1945, Japan surrendered, and lost its huge Pacific empire.

Nuclear testing. After World War II, the United States began nuclear weapons tests on Bikini and Enewetak atolls in Micronesia and on Kiritimati Atoll (Christmas Island) and Johnston Island in Polynesia. The British conducted similar tests on Kiritimati Atoll. In 1963, the two countries and the Soviet Union signed a treaty banning aboveground nuclear tests. The United States and the U.K. then stopped their tests in the Pacific. France also has nuclear weapons but did not sign the test-ban treaty. From 1965 to 1996, France tested nuclear weapons in French Polynesia from time to time.

Recent developments. An organization called the Pacific Community has helped promote the islands' economic and social welfare. It was founded as the South Pacific Commission in 1947 by Australia, the United Kingdom, France, the Netherlands, New Zealand, and the United States. The Netherlands withdrew in 1962, after Indonesia took control of Dutch (West) New Guinea. Today, the organization includes most of the islands. But the newly independent nations have complained that the Pacific Community is dominated by its powerful members. As a result, the Cook Islands, Fiji, Nauru, Tonga, and Western Samoa (now Samoa) organized the South Pacific Forum in 1971 to promote cooperation among themselves in such matters as international relations and trade. Australia and New Zealand were included as Forum members due to their location and their involvement in the region's affairs. As other islands gain self-government, they have been invited to join the Forum. Forum members hope that by cooperating with one another they will depend less on Western nations.

Since 1962, some Pacific islands or island groups have become independent, and others have been working toward this goal. The British granted full independence to Fiji and Tonga in 1970 and to the southern Solomon Islands and to Tuvalu (formerly Ellice Islands) in 1978. In 1979, the United Kingdom's Gilbert Islands dependency became the independent nation of Kiribati. In 1980, the New Hebrides—which had been ruled jointly by the U.K. and France—became independent as Vanuatu.

In 1965, the Cook Islands—a territory of New Zealand—gained a form of self-government. The islands control internal affairs, and New Zealand handles external affairs as requested. Another New Zealand territory, the island of Niue, gained self-government in 1974.

After World War II, the United Nations (UN) decided that four areas in the Pacific should be governed as trust territories until they were ready for independence. New Zealand administered Western Samoa as a trust terri-

tory until 1962, when it gained independence. Western Samoa changed its name to Samoa in 1997. Australia, Britain, and New Zealand governed Nauru as a trust territory until 1968, when it became independent. The Trust Territory of New Guinea was governed by Australia until 1973, when it became part of the self-governing territory of Papua New Guinea. Papua New Guinea gained full independence in 1975.

The United States administered the Trust Territory of the Pacific Islands, which was divided into four political units. In 1986, all of the Mariana Islands except Guam became a commonwealth of the United States. Guam is a U.S. territory. Also in 1986, the Marshall Islands and the Federated States of Micronesia—comprised of all of the Caroline Islands except the Palau group—became independent nations in free association with the United States. Under free association, their governments control all of their internal and foreign affairs. However, the United States is obligated to defend the islands in emergency situations. In 1994, the Palau Islands became the independent nation of Palau. The new country also had an arrangement of free association with the United States. Robert C. Kiste

Pacific Islands, Trust Territory of the, was a territory administered by the United States under the approval of the United Nations (UN). The territory was established by the UN in 1947. It ceased to exist in 1994.

The trust territory originally consisted of the Caroline and Marshall islands, and all the Mariana Islands except Guam, which was already a U.S. possession. These island groups all belong to a larger area in the western Pacific Ocean called Micronesia. The islands of the territory were seized from Japan by the United States during World War II (1939-1945).

Under the terms of the trusteeship agreement with the UN, the United States assumed responsibility for the political, economic, social, and educational development of the islands. In return, the United States was recognized as the sole administering authority for the area. It was given the right to govern the territory according to its laws and to build military facilities where and when necessary. The U.S. Navy administered the Trust Territory for the United States until 1951, when administrative responsibility passed to the U.S. Department of the Interior.

Through the years, calls for self-government by the people of the territory grew. In 1969, the U.S. government and representatives from the islands began negotiations to end the trusteeship. In 1975, the Northern Marianas became a self-governing U.S. commonwealth. In 1979, four local districts in the Caroline Islands—Kosrae, Ponape (now Pohnpei), Truk (now Chuuk), and Yap—joined together and adopted a constitution to form the Federated States of Micronesia. Palau and the Marshall Islands declared themselves republics in 1979.

In 1982, Palau, the Federated States of Micronesia, and the Marshall Islands signed compacts of free association with the United States. Under these compacts, the three governments control their internal and foreign affairs. However, the United States is responsible for the defense of the islands and is obligated to provide them with financial assistance. The compacts between the United States and the Federated States of Micronesia and the Marshall Islands took effect in 1986. Palau became totally self-governing in 1994, thereby ending the Trust Territory of the Pacific Islands. David Hanlon

Pacific Northwest includes all of Oregon, Washington, and Idaho, and western Montana. The region varies greatly. Part of the Rocky Mountain system stands in the east, in Montana, Idaho, and Washington. The well-populated Willamette Valley of Oregon and the Puget Lowland of Washington are located to the west. In the middle lies the Columbia Plateau of Idaho, Oregon, and Washington. The Pacific Northwest is a major source of forest products, fruits, grain, minerals, and potatoes. Harley Johansen

Pacific Ocean is the largest body of water in the world. The ocean covers about 66 million square miles (171 million square kilometers). That area represents over 45 percent of the total area of all the oceans and about one-third of Earth's total surface area. Thousands of islands lie in the Pacific Ocean. They range from island nations, such as Japan and New Zealand, to the hundreds of small, scattered islands in the central and southern Pacific. The Pacific Ocean is a source of many natural resources, including seafood, petroleum, and minerals.

The word *pacific* means *peaceful.* The ocean received this name from the Portuguese explorer Ferdinand Magellan, who sailed its waters for several months, driven by gentle winds. But the Pacific is often far from peaceful. Typhoons and hurricanes in the Pacific have wrecked fleets of ships and destroyed island cities. Earthquakes and volcanic eruptions deep in the sea have created destructive waves called *tsunamis* (pronounced *tsoo NAH meez).* In the open ocean, those waves are hardly noticeable because of their small height. When the waves reach the shore, however, the waters can pile up to a height of more than 100 feet (30 meters).

In 1513, the Spanish explorer Vasco Núñez de Balboa crossed the Isthmus of Panama and became the first European to see the eastern Pacific. Magellan was the first European to sail across the ocean. He crossed it from November 1520 to April 1521. In the 1760's and 1770's, Captain James Cook of the British Navy explored and mapped much of the Pacific. He probably was the first European to visit the Hawaiian Islands, Australia, and New Zealand.

Boundaries. The Bering Strait between Russia and Alaska marks the northern end of the Pacific Ocean. The eastern border of the Pacific Ocean is North and South America. To the west lie the mainland of Asia and the countries Indonesia and Australia. The southern limit of the Pacific is the line of 60° south latitude. South of that line is the Southern Ocean, also known as the Antarctic Ocean.

A number of seas, called *marginal seas,* are part of the Pacific Ocean. Those include the Bering Sea, the Sea of Japan (also called the East Sea), the East China Sea, and the Tasman Sea.

The ocean floor. The depth of the Pacific Ocean varies greatly from place to place. On the ocean floor are high mountains, ridges, vast plains, and extremely deep areas called *trenches.*

One underwater mountain range, the East Pacific Rise, extends from north of Antarctica to the coast of Mexico. The height of the East Pacific Rise above the ocean floor varies from about 6,500 to 10,000 feet (2,000 to 3,000 meters). In many parts of the Pacific, volcanic eruptions have created peaks called *seamounts.* Some seamounts rise above the surface of the water, forming islands.

The deepest parts of the Pacific Ocean are in the trenches. Most of the trenches are from 20,000 to 30,000 feet (6,000 to 9,000 meters) deep. The Mariana Trench, near Guam, includes the Challenger Deep, the deepest known spot in any ocean. The Challenger Deep extends 35,840 feet (10,924 meters) below the water's surface.

Chimneylike structures called *hot vents,* or *hydrothermal vents,* lie mainly in the eastern Pacific. Those structures occur as a result of ocean water seeping down through cracks in the ocean bottom. Underlying rock heats the water, which then rises back to the ocean floor to create mineral-rich springs. See **Hot vent.**

A shallow region of ocean floor called a *continental shelf* extends off the shore of each continent bordering the Pacific. The water on the continental shelves is usually less than 660 feet (200 meters) deep.

Climate. The North Pacific has long, cold winters and short, cool summers. Along the equator, the climate is hot all year. In much of the South Pacific, summers are mild, and winters are cool. In the southernmost part of the Pacific, winters are cold and stormy.

Winds over the Pacific include the *trade winds* and the *prevailing westerlies.* In both the Northern and Southern hemispheres, the trade winds blow from about 30° latitude toward the equator. They come out of the northeast in the Northern Hemisphere and out of the southeast in the Southern Hemisphere. The prevailing westerlies blow from the west between the latitudes of 30° and 60° in both hemispheres. They produce stormy belts of precipitation at about 60° and areas of little precipitation at about 30°. See **Trade wind; Prevailing westerly.**

Tropical cyclones are great circular winds that produce much of the rainfall in the Pacific area. They usually cause little or no damage, and they may bring needed rain to dry areas. However, they occasionally reach such high speeds that they become destructive. A cyclone whose speed reaches 74 miles per hour (119 kilometers per hour) is called a *typhoon* in the northwestern Pacific and a *hurricane* in the northeastern Pacific. Near Australia, it is called a *tropical cyclone.* See **Cyclone; Hurricane; Typhoon.**

El Niño. About every two to seven years, a climate change occurs in the Pacific between 20° north latitude and 20° south latitude. In normal times, the trade winds blow the surface waters from east to west. In the east, deeper cold water rises to the surface to replace the water that is blown away. The cold water is rich in nutrients that increase the growth of the *plankton*—a mass of tiny animals and plantlike organisms that drift with the currents. The plankton, in turn, supports a huge population of fish. As a result, the waters off Ecuador and Peru are one of the world's largest commercial fishing areas.

When the climate changes, the east-to-west winds weaken or may even reverse. As a result, the waters off Ecuador and Peru become abnormally warm. Cold, nutrient-rich water no longer rises to the surface, so the fish population declines sharply.

The interaction of the atmosphere and the ocean during this abnormal period is known as an *El Niño.* During an El Niño, the coast of South America becomes wetter

Facts in brief

Area: About 66 million square miles (171 million square kilometers).

Greatest distances: *North-south*—about 8,570 miles (13,800 kilometers). *East-west*—about 11,000 miles (17,000 kilometers).

Greatest depth: 35,840 feet (10,924 meters), in the Challenger Deep.

Surface temperatures: *Highest,* 88 °F (31 °C), near the equator and in the western marginal seas in summer. *Lowest,* About 32 °F (0 °C), at high latitudes in winter.

than normal, and the climate in Indonesia and other nations of Southeast Asia is unusually dry. An El Niño usually begins in the early summer of one year and extends into the spring of the next year.

An opposite effect called *La Niña* can also occur. During a La Niña, the water in the eastern Pacific, for example, is cooler than it is when there is merely no El Niño.

Both El Niño and La Niña are part of a larger atmospheric pattern known as the *Southern Oscillation.* Oceanic and atmospheric scientists now refer to El Niño as the ENSO (El Niño-Southern Oscillation). See **El Niño.**

Currents. The surface currents in most of the Pacific Ocean are parts of two gigantic, rotating systems of current known as *gyres.* One gyre is centered at about 30° north latitude and rotates clockwise. The other is centered at about 30° south latitude and rotates counterclockwise. Trade winds and prevailing westerlies drive both gyres.

In the Northern Hemisphere, the North Equatorial Current carries warm water from Central America west to the Philippine Sea. There, the gyre turns north as the Kuroshio, or Japan Current, which warms Japan. The North Pacific Current travels east across the ocean and warms western Canada.

In the Southern Hemisphere, the warm South Equatorial Current flows from South America to about the Solomon Islands. From there, the East Australian Current carries warm water south along the coast of Australia and to New Zealand. The Peru Current, also called the Humboldt Current, carries cool water north along the coast of South America to about Ecuador and Peru.

Water masses. Beneath the ocean surface are *water masses,* layers of water with different patterns of circulation. The North Pacific Intermediate Water forms near the surface in the northwestern Pacific. The water becomes cold and dense, so it sinks to greater depths. At depths of 1,600 to 2,600 feet (500 to 800 meters), it spreads out. The North Pacific Intermediate Water flows south to about the equator.

The Antarctic Intermediate Water forms near the southern boundary of the Pacific. It extends northward to about the equator at depths of 1,300 to 4,000 feet (400 to 1,200 meters). The Antarctic Intermediate Water also pushes into the Atlantic and Indian oceans.

Beneath the two intermediate layers is the Pacific Deep Water, whose depth ranges from about 5,000 to 11,000 feet (1,500 to 3,400 meters). This layer moves from north to south throughout the Pacific. The deepest layer is the Pacific Bottom Water. This mass enters the Pacific from the Southern Ocean and flows northward to the northeast Pacific.

Tides. Large tides occur along the Pacific rim. Some of the largest form off the west coast of Korea. There, the water is 15 to 30 feet (4.6 to 9.0 meters) deeper at high tide than at low tide. In mid-ocean, tides are small. For example, at Midway Island, the water level varies by about 1 foot (0.3 meter). See **Tide.**

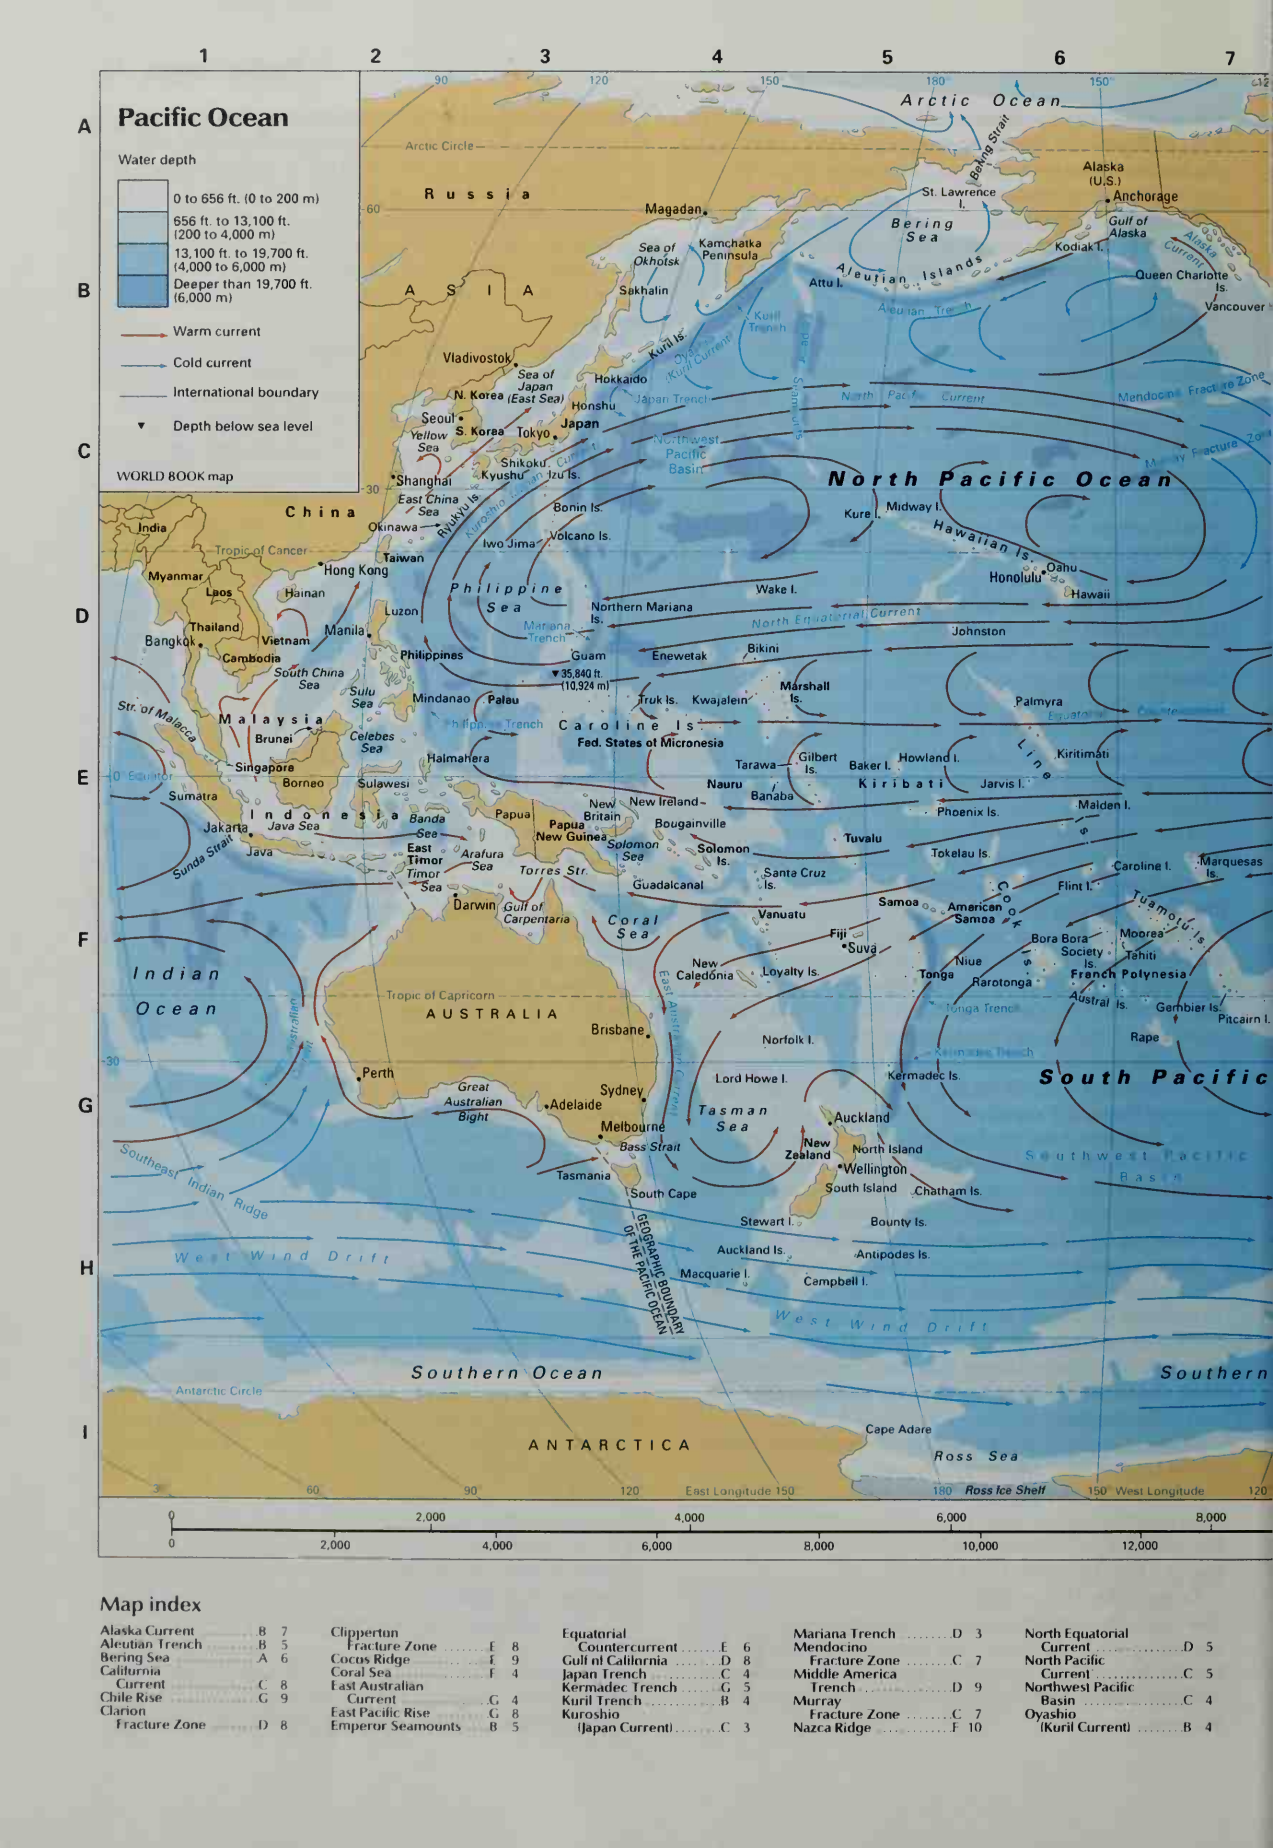
Ocean life. The oceans contain a complex food web that involves plankton; bacteria; fish; marine mammals, including seals, dolphins, and whales; and animals that live on the seafloor. Seaweeds grow on the seabed in shallow waters. In the tropics, coral reefs support a diverse ecosystem.

An upwelling of water from depths of about 160 to 650 feet (50 to 200 meters) provides nutrients that support ocean life. The cooler subsurface waters are rich in chemical elements and compounds that serve as food for *phytoplankton* (plantlike plankton). *Zooplankton* (planktonic animals) feed on the phytoplankton. Fish, in turn, eat the zooplankton. The major areas of upwelling in the Pacific lie along the coasts of North and South America.

Clams and mussels almost 1 foot (0.3 meter) long and tube worms up to about 10 feet (3 meters) in length live near hot vents. Also living in those areas are species of crabs, fish, and shrimp that are found nowhere else.

Resources. The Pacific provides about half the world's catch of fish and shellfish. Fishing crews in the Pacific harvest more than 50 million tons (45 million metric tons) of seafood annually. About half the catch comes from the northwest Pacific—near China, Japan, and Russia. Other major fishing areas include waters near Southeast Asia, Australia, South America, and North America.

Other products of the Pacific include pearls, seaweed used for fertilizer and in processed foods, tropical fish for aquariums, and minerals. An important source of seafood along the Pacific rim is fish farming, also called *aquaculture* or *mariculture.* Farmers raise fish, shellfish, and seaweeds near ocean shores as well as in ponds.



Prospectors have discovered major deposits of petroleum in coastal waters off California, Southeast Asia, and Australia. Offshore oil wells operate in those waters. Natural gas comes from wells on the continental shelves near Russia, Southeast Asia, and Australia.

On the Pacific seafloor are potentially valuable chunks of material known as *manganese nodules.* The nodules are shaped like slightly flattened balls, and most are 2 to 4 inches (5 to 10 centimeters) in diameter. They are about 15 to 30 percent manganese, a metal that is used in the manufacture of steel. The nodules are also 5 to 20 percent iron, and they contain significant amounts of nickel, copper, and cobalt.

Scientific research. Between 1872 and 1876, oceanographers aboard the British scientific ship *Challenger* became the first to study the ocean floor thoroughly. The researchers obtained samples of deep-sea organisms and seabed materials from the Pacific and other areas. They also measured the depth of the seafloor by lowering ropes to the bottom. Scientists continued to measure depth in that way until the early 1900's. At that time, they began to use *sonar,* a process that utilizes sound waves to measure distance.

In 1960, Donald Walsh of the United States Navy and Jacques Piccard, a Belgian oceanographer, descended 35,800 feet (10,900 meters) in the Mariana Trench aboard a *bathyscaph* (diving craft) named *Trieste.* Theirs was the deepest dive ever recorded. In the mid-1970's, geochemists conducted an extensive study of the properties of the intermediate, deep, and bottom waters of the oceans. In 1977, scientists aboard the research submersible *Alvin* made the first discovery of a hot vent. They found the vent on the Galapagos Rift west of Ecuador.

In the 1990's, extensive studies of the Pacific and the other oceans continued. One of the largest was part of an international project called the World Ocean Circula-

tion Experiment (WOCE). Two major goals of WOCE were (1) to develop and test *computer models* useful for predicting climate change and (2) to develop methods for monitoring long-term changes in ocean circulation. A computer model is a set of mathematical equations processed by computers. In this case, the equations *simulate* (represent) how climate changes.

Scientists want to develop such models to learn more about why the temperature of the air at the earth's surface is becoming warmer. Continued warming could cause environmental and economic damage.

Most of the warming is almost certainly due to human activities, mainly the burning of *fossil fuels* (coal, oil, and natural gas). The burning releases carbon dioxide (CO_2) gas into the atmosphere. Atmospheric CO_2 can increase the surface temperature via a complex process known as the *greenhouse effect.* Researchers are studying the oceans because the oceans absorb atmospheric CO_2. See **Global warming; Greenhouse effect.**

Damage to reefs. Global warming may already be damaging coral reefs. An increase in air temperature raises ocean temperatures, and coral reefs are sensitive to a warming of the water.

A coral reef consists of a mass of the limestone skeletons of small animals called *polyps,* a layer of live polyps attached to the mass and to one another, and algae that live in the polyps' tissue. The algae produce and release substances that serve as food for the polyps. The algae also give coral reefs their distinctive colors.

But when the water becomes unusually warm, the polyps release their algae. As a result, the polyps turn white; they are said to be *bleached.* If the water temperature does not return to normal soon enough, the polyps will die. See **Coral reef.**

Offshore pollution has harmed creatures that live in the Pacific Ocean. Pollutants flow into the ocean from the land and rivers. The pollutants include industrial chemicals, petroleum products, sewage wastes, and artificial fertilizers. Some of those substances contain nutrients and increase the growth of algae in the ocean. Bacteria break down other substances in the water, releasing nutrients.

Even when little or no pollution is present, algae can accumulate into thick layers called *blooms.* Certain algae in the blooms can produce poisons that harm other marine organisms. Those substances can also harm people who eat them in seafood. Many scientists think that nutrients in polluted water cause algae to multiply rapidly, creating extremely thick blooms often called *red tides.* As a result, the poisons can build up to dangerous levels. In the Pacific, huge blooms have occurred near Japan and China. See **Water pollution.** Dana R. Kester

Pacifism is a belief that rejects the use of violence. Many pacifists are opposed either to certain wars or to all wars. But in its strictest sense, pacifism means opposition to all violence—even in self-defense—and is called *nonresistance.* The word *pacifism* was coined by Émile Arnaud, a French statesman, in 1901 at the 10th Universal Peace Congress in Glasgow, Scotland. Arnaud was describing the beliefs of men and women who urged the use of international law and diplomacy, instead of war, to settle conflicts among nations.

During World War I (1914-1918), the meaning of the term shifted, especially in the United States and the United Kingdom. At that time, the word came to represent the opposition to all wars, called *absolute pacifism,* or to specific wars. Pacifist groups opposed United States participation in World War I and supported *conscientious objectors*—people whose consciences do not let them take up arms during warfare.

Pacifism has been associated with such major religions as Buddhism, Hinduism, and Christianity. Since the 1600's, the Quakers have been the religious group most closely associated with the belief. Many pacifists, whether religious or not, consider the use of force as degrading to human nature. In addition, pacifists object to the unreasonable and destructive elements of war.

During the 1920's and 1930's, between World Wars I and II, absolute pacifists in the United States and the United Kingdom developed strong antiwar movements. Pacifists supported the organization of the United Nations after World War II ended in 1945.

From the 1950's through the 1980's, European pacifists mounted a series of protests against the nuclear arms race between Western and Communist nations. In the United States during the 1960's and early 1970's, pacifists helped lead the opposition to U.S. participation in the Vietnam War.

Pacifist techniques have also been used to bring about social change. Mohandas K. Gandhi, the leader of India's struggle for independence from the United Kingdom, strongly opposed the use of violence. Instead, he organized nonviolent disobedience to British laws that he believed were unfair. Gandhi's approach became known as *nonviolent resistance* or *Satyagraha.*

During the 1950's and the 1960's, civil rights leader Martin Luther King, Jr., applied Gandhi's approach in working for equality for American blacks. The technique, now known as *nonviolent action,* has been applied elsewhere as well. It was used by some blacks in South Africa before the country was freed in the 1990's from minority white rule. Pacino, *puh CHEE noh,* **Al** (1940-), is an American actor known for his brooding, intense acting style. Pacino gained fame in the *Godfather* trilogy of motion pictures. Pacino played Michael Corleone, who becomes the head of a vast organized crime operation. The trilogy consisted of *The Godfather* (1972), *The Godfather, Part II* (1974), and *The Godfather, Part III* (1990). Pacino won the 1992 Academy Award as best actor for his performance in *Scent of a Woman.*

Alfredo Pacino was born in New York City. He dropped out of school at the age of 17 and lived on odd jobs for several years before enrolling in acting school. He won acting awards on Broadway and off-Broadway for his performances in *The Indian Wants the Bronx* (1968) and *The Basic Training of Pavlo Hummel* (1977). He made his movie debut in *Me Natalie* (1969).

Pacino's performance as a drug addict in *The Panic in Needle Park* (1971) led to his being cast in the *Godfather* films. Pacino's other major movies include *Serpico* (1973), *Dog Day Afternoon* (1975), *Scarface* (1983), *Sea of Love* (1989), *Dick Tracy* (1990), *Frankie and Johnny* (1991), *Glengarry Glen Ross* (1992), *City Hall* (1996), the documentary *Looking for Richard* (which he also directed and produced, 1996), *Donnie Brasco* (1997), and *The Insider* (1999). Pack rat. See **Woodrat.**

Packaging is a process essential for the containment and protection of goods. Almost everything that is grown, manufactured, and sold is packaged at some time. Packaging also makes it easy for consumers, shop owners, and distributors to handle products. A package provides information about a product and identifies the product with a distinctive shape, color, and design.

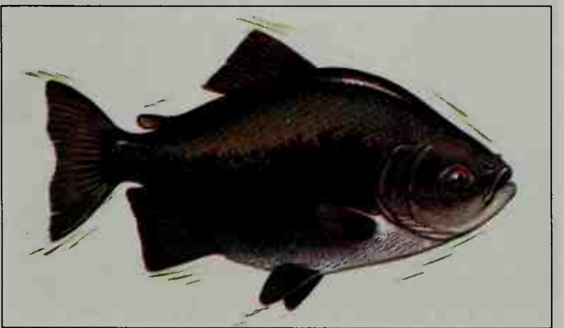
Types of packages include bags, bottles, boxes, crates, drums, pallets, pouches, and sacks. The most commonly used packaging is made of paper and paperboard, such as corrugated boxes, folding cartons, and *composite cans* (paperboard tubes with metal bases). Other major types of packaging include metal packaging, such as aluminum and steel cans; flexible packaging, including aluminum foil and flexible plastic pouches; rigid plastics, which are used in bottles, trays, and caps; and glass.

Manufacturers and designers have developed packages with many convenient features, such as resealable zipper closures and easy-open caps. Lightweight *stand-up pouches* can take the place of cartons and bottles. *Easy open/reseal* and *dosage indicator* caps are used for over-the-counter and prescription drugs. *Modified atmosphere packages* maintain conditions that help prevent the deterioration of such products as premixed salads. *Aseptic packages* are filled in a sterile environment after both the packaging and the product have been sterilized. Such packages are used for medical supplies and such products as milk and fruit drinks. Some containers for use in microwave ovens are made from *susceptor materials.* Such materials help direct microwave energy inside the package to crisp and brown the crust of pizzas or French fries.

The packaging industry is a multibillion-dollar industry worldwide. Suppliers sell finished packaging to industries or organizations, or directly to consumers.

More than half of all packaging is used for food and beverages. Most of the rest is used for other consumer products. Industrial products, such as chemicals and petroleum, use only a small portion of all packaging.

Packaging represents nearly a third of all solid waste production. Thinner, lighter packaging materials and reusable packages can reduce packaging wastes. Recycling also helps reduce wastes. Most packaging materials have some recycled content. *Biodegradable* materials break down in an environment where oxygen, light, and water are available, such as a compost pile (see **Compost**). But most wastes end up in sanitary landfills, where these conditions generally do not exist. Incineration is another option for package disposal. Some plastics produce more energy than coal when burned.



Packaging regulations. Many countries, including the United States, require that every package be accurately labeled to identify the product, the quantity of the contents, and the name and location of the manufacturer, packer, or distributor. The label must describe the nutritional content of any product portrayed as having special nutritional value.

In the United States, the Federal Trade Commission (FTC) and the Food and Drug Administration (FDA) regulate the labeling of consumer products. The FDA approves new materials and additives for use with food packaging. It requires *tamper-resistant,* also called *tamper-evident,* packaging for nonprescription drugs and certain related products. The Consumer Product Safety Commission establishes guidelines for child-resistant packaging and labels for hazardous household products. D. Kay Cooksey

Pacu, *PA kyoo,* is the common name for several species of South American freshwater fish. Pacus have a narrow, plate-shaped body. Some pacus look much like piranhas, to which they are closely related. However, unlike piranhas, pacus have blunt teeth and eat plants and *plankton* (small, drifting water organisms). Piranhas have sharp teeth and eat fish. Some small pacus are popular for home aquariums.

WORLD BOOK illustration by John F. Eggert

The black pacu is an important food fish in Brazil.

The *black pacu* may grow to more than 3 feet (90 centimeters) long and weigh over 65 pounds (30 kilograms). It is found in rivers throughout the Amazon region. In Brazil, where it is called *tambaqui,* the black pacu is an important commercial food fish. During the long rainy season, adult black pacus migrate far from the main branches of the Amazon River into flooded parts of the tropical forest. There they eat seeds and fruits that fall into the water. When the floodwaters go down, black pacus return to the main river channels. They stay there, eating little, until the next rainy season. Tomio Iwamoto

Scientific classification. Pacus belong to the characin family, Characidae. The scientific name for the black pacu is *Colossoma macropomum.*

Paddlefish is a fish that lives in the rivers and reservoirs of the Mississippi River drainage system. It is a member of a primitive group of fishes having sharklike fins and an oarlike snout that extends out over the mouth. This snout gives the fish its name. The only other surviving member of its family lives in rivers of China. The American paddlefish grows to more than 6 feet (1.8 meters) long and weighs up to 90 pounds (41 kilograms).

The paddlelike snout may be a sense organ, possibly used in locating the tiny organisms called *plankton* on which this fish feeds. The paddlefish catches food by straining water over its gills. A good quality of caviar is made from the fish's *roe* (eggs). The fish's flesh also is valued as food. The paddlefish is also known as the *spoon-billed catfish.* Robert D. Hoyt

Scientific classification. The American paddlefish belongs to the family Polyodontidae. It is *Polyodon spathula.*

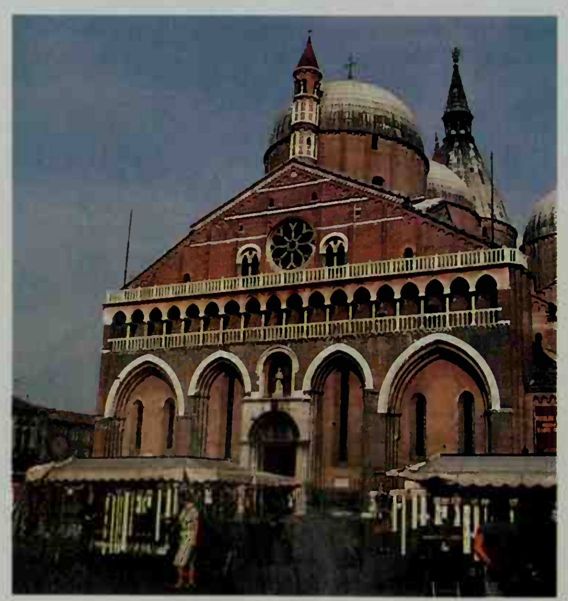
Paderewski, *PAD uh REHF skee,* **Ignace Jan,** *EE nyas yahn* (1860-1941), was a Polish pianist, composer, and statesman. During World War I (1914-1918), he left his career as a musician to devote himself to the cause of Polish freedom. At the close of the war, Poland again became independent, largely because of his efforts.

Child prodigy. Paderewski was born in Podolia, now a part of Ukraine. His father was an administrator of estates. His mother was the daughter of a professor. He began his piano lessons at the age of 6. When he was 12, he entered the Warsaw Conservatory. Six years later, he was appointed a professor there.

Paderewski became a pupil of Theodor Leschetizky in Vienna in 1884. In 1887, he began a brilliant career as a concert pianist, playing to enthusiastic audiences in Europe and America. American audiences heard him for the first time in 1891 in New York City. He also played in South America, Australia, New Zealand, and South Africa, as well as throughout Europe. The proceeds of many of his concerts went to charity. He set up the Paderewski Foundation for young composers in 1896 in the United States, and founded two competitions in Warsaw in 1898, for composition and drama. In 1897, Paderewski bought an estate in Switzerland and lived there in his later years.

Polish patriot. Paderewski's devotion to Poland is now a part of history. During World War I, he gave concerts to raise relief funds and helped enlist men for the Polish Army. He represented Poland at the Versailles Peace Conference and the League of Nations. He served as premier, as well as minister of foreign affairs, in the

Polish republic. But political disputes arose, and Paderewski and his cabinet stayed in power only 10 months.



Later career. In 1922, Paderewski resumed his concert performances and teaching. He had given away most of the money he had previously earned to help Poland. He made his last American tour in 1939. After suffering a mild heart attack, he returned to Switzerland. A few months later, Germany invaded Poland, and World War II began. Once more Paderewski devoted himself to the cause of Poland. He was named president of the new Polish Parliament in exile, later called the Polish National Council. Late in 1940, he returned to the United States to make his home on a California ranch. He died in New York City.

Paderewski's compositions include the opera *Manru,* Sonata in A minor for violin and piano, six humoresques for piano, and "Polish Fantasy" and Concerto in A minor for piano and orchestra. His last composition, Symphony in B minor, is a musical picture of the tragic history of Poland. Lydia Hailparn Ledeen

Padre Island is a barrier island that stretches for about 100 miles (160 kilometers) along the south Texas coast. Laguna Madre, an *estuary* (lagoon), separates it from the mainland (see **Texas** [physical map]). Causeways give access to Corpus Christi and Port Isabel, near Brownsville. Brazos Santiago Pass and the Mansfield Channel connect Laguna Madre to the Gulf of Mexico. The island is a recreational center and wildlife habitat. In 1962, a national seashore was authorized for Padre Island. The island was named for Padre (Father) Nicolás Balli, a Spanish priest who started a ranch there about 1800. Padua, *PAD yoo uh* (pop. 215,137), stands on the Bacchiglione River, 22 miles (35 kilometers) southwest of Venice (see **Italy** [political map]). It is the oldest city in northern Italy, and its history is rich in architecture, art, and famous people. Many of Padua's narrow, crooked streets are lined with arcades, and several high Roman bridges cross the various arms of the river. The city has many medieval palaces and churches. The Basilica of St. Anthony is a church that dates from the 1200's.

Padua is the oldest city in northern Italy. The Basilica of St. Anthony, *shown here,* is one of many medieval palaces and churches in the city. The basilica dates from the 1200's.

Padua's art treasures include works by such well-known masters as Giotto, Donatello, and Fra Filippo Lippi. The Roman historian Livy was born in Padua, and at one time Dante lived there. Galileo lectured for 18 years in Padua's university, which was founded in 1222 by Emperor Frederick II. A celebrated botanical garden, the oldest in Europe, is connected with the university.

Today Padua manufactures automobile parts, refrigerators, and other machinery. It has a prosperous trade in fruit, grain, wine, and cattle. Anthony James Joes

Paganini, *PAG uh NEE nee,* **Niccolò,** *NEEK koh LAW* (1782-1840), became one of the greatest violinists of all time. He was just 9 years old when he made his concert debut in Genoa, Italy. From the age of 13, Paganini enjoyed triumphant concert tours. Paganini played quiet melodies so beautifully that his audiences often burst into tears. But he could also perform with such force and speed that a fantastic story began to circulate that he was in league with the Devil, who guided his bow.

Once Paganini won his fame, his life became a combination of artistic triumphs and extravagant living. He once pawned his violin to pay a gambling debt. A French merchant gave him one made by Giuseppe Guarnieri, so that he could play a concert. Paganini left this violin to Genoa, where it is kept in a museum.

At the age of 13, Paganini began to compose pieces for the violin. His works include 24 caprices for violin; two concertos for violin and orchestra, in D major and B minor; and *Moto Perpetuo (Perpetual Motion).* Paganini was born in Genoa on Oct. 27, 1782. Stephen Clapp

Pager, also called a *beeper,* is a small, wearable device that enables the carrier to receive brief messages while on the move. The idea behind pagers originated with police radio communications in the 1920's. During the 1970's, individuals began carrying pagers for personal use.

A pager is actually a small radio receiver that responds with a tone or vibration when activated by a radio signal. Each pager has its own identification number. A caller can dial the pager number from a telephone or from a computer attached to a modem. The resulting signals travel through the telephone network to a paging terminal. At the terminal, the signals are coded and sent by wire or radio to paging transmitters in the coverage area. The transmitters broadcast the message as a radio signal on a frequency dedicated to the paging service.

Pagoda, *puh GOH duh,* is a type of tower commonly associated with Buddhist temples. Pagodas exist mainly in China, Japan, and parts of India and southeastern Asia. A typical pagoda has from 3 to 15 stories that decrease in size from bottom to top. Each story of the tower features an overhanging, elaborately decorated tile roof that curves upward at the edges. In many cases, fanci-

fully carved wooden beams and posts support the structure.

In China, most pagodas have eight sides and an uneven number of stories. They are made of wood, masonry, glazed tile, or porcelain and are decorated with ivory, bone, and stonework. Originally, each element in the design of a pagoda had religious meaning. Many Chinese people believed a pagoda brought wealth and happiness to the surrounding community. Japanese pagodas developed from Chinese models. Most Japanese pagodas are made of wood. The ground story may contain shrines and images, and the pagoda's upper stories may be used to view the surrounding area. In Taiwan, many of the pagodas house the ashes of cremated Buddhists.

A pagoda in Nanjing, China, *shown here,* was built in the 1920's. The nine-story structure has a steel frame and masonry walls.

Pagodas originated in India from the form of Buddhist burial mounds and temples called *stupas.* As Buddhism spread eastward, the pagoda form spread with it. Beginning in the 1600's, imitation pagodas were built in many European gardens. William J. Hennessey

Paige, Satchel (1906?-1982), was one of the greatest pitchers in baseball history. He pitched for touring black teams and teams in the Negro leagues for more than 20 years at a time when blacks were not allowed to play in the major leagues. Paige was past his prime when he joined the Cleveland Indians in 1948 and became the first black pitcher in the American League. He won 6 games and lost 1 that season and helped Cleveland win the pennant. Paige also pitched for Cleveland in 1949 and for the St. Louis Browns from 1951 to 1953. He made a final appearance in 1965, pitching in one game for the Kansas City Athletics. Paige's career major league record was 28 victories and 31 defeats.

Paige was born in Mobile, Alabama. His full name was LeRoy Robert Paige. The exact year of his birth is unknown. Paige earned the nickname of *Satchel* from carrying satchels at the Mobile railroad depot as a boy. He began playing baseball professionally in 1924, and often pitched against major leaguers in exhibition games. In 1937, New York Yankee star Joe DiMaggio called him the greatest pitcher he ever faced. Paige also became famous for his homespun humor. In 1971, Paige was elected to the National Baseball Hall of Fame.

Pain is an unpleasant sensation that can range from a mild annoyance to an overpowering experience. Pain warns the body about dangerous situations or injuries. Pain that occurs suddenly and fades within hours, days, or weeks after the underlying cause is corrected is called *acute* pain. Acute pain helps survival because people react by trying to avoid the harmful circumstances that cause it. For example, people automatically pull their hands away from an unexpectedly hot object.

Pain that lasts more than a few months is called *chronic* pain. In some cases, the circumstances that cause pain cannot easily be corrected. For example, many people have pain from conditions that cannot be cured, such as arthritis, cancer, and diabetes. The number of people living with chronic pain has grown because the human life span has increased. Many long-term diseases that cause chronic pain become more common as people age. Chronic discomfort interferes with sleep and can lead to depression. Diagnosing and treating chronic pain has gained importance as a medical challenge.

How the body feels pain. Pain is a highly personal experience that involves physical events and psychological factors. No one experiences pain in exactly the same way as anyone else. Pain begins in specialized nerves called *receptors.* Receptors detect sensations of cold, warmth, pressure, and chemical irritation in the body's skin, muscles, blood vessels, and bones. When such sensations become strong enough to damage tissue, cells in the injured area leak certain chemicals. These chemicals activate receptors to send a pain message.

The receptors convert the chemical into an electrical signal. The signal then travels along pain nerves to the spinal cord, and, finally, to the brain. When the message reaches the brain, the person becomes aware of pain.

The path from receptors to the brain is complicated. There are three different types of pain nerves that carry signals from receptors to the spinal cord. In the spinal cord, there are two pain pathways to the brain—one chiefly for acute pain and one chiefly for chronic pain.

Between nerves, there is a tiny gap called a *synapse (sih NAPS).* When the electrical pain signal reaches the end of a nerve, it stimulates the release of chemicals into the synapse. These chemicals cross the synapse and create another electrical message in the next nerve. Many nerves can release chemicals at a particular synapse. The gaps thus provide an opportunity for signals to influence one another as they travel to the brain.

Pain can also be influenced by such psychological factors as excitement or fear. For example, athletes who are extremely excited about a game may be injured without realizing it and continue to play. In contrast, the pain of a medical procedure may be increased by a patient's anticipation and fear of the experience.

Treating pain. Treatment for acute pain aims to remove its cause and provide relief while the body heals. For example, doctors treat a broken leg by setting the bone and giving drugs until the pain of the break subsides. The drugs most commonly prescribed for acute pain include acetaminophen (for example, Tylenol) and a group of drugs called *nonsteroidal anti-inflammatory drugs,* often abbreviated NSAID's (pronounced *EHN sehdz).* Aspirin is the most familiar NSAID. The group also includes such drugs as ibuprofen, sold under Advil, Motrin, and other trade names. For extreme acute pain—for example, after surgery—doctors may prescribe narcotic drugs, such as morphine. Narcotics are also called *opioids (OH pee oydz).*

Doctors use a variety of treatments for chronic pain. Drugs called *antidepressants* may help control chronic pain and improve depression and sleep. Other drugs commonly used to treat seizures also help some patients. In the most severe cases, doctors may prescribe long-term use of narcotics. Narcotics can be taken in several ways, including by mouth or by skin patch. They may also be injected into a vein, a muscle, or directly into the space around the spinal cord. Nelson H. Hendler

Paine, Robert Treat (1731-1814), an American statesman, was a Massachusetts signer of the Declaration of Independence in 1776. He had been a Massachusetts delegate to the Continental Congress from 1774 to 1776. Paine served as the first attorney general of his state from 1777 to 1790. He helped write the state's Constitution, which was adopted in 1780. He served as a justice of the state supreme court from 1790 to 1804. Paine was born in Boston and graduated from Harvard in 1749. He became a lawyer in 1757. In 1780, he helped found the American Academy of Arts and Sciences. Jack N. Rakove

Paine, Thomas (1737-1809), was a famous pamphleteer, agitator, and writer on politics and religion. His writings greatly influenced the political thinking of the leaders of the Revolutionary War in America (1775-1783), and he became a famous figure in Paris during the French Revolution. "I know not," wrote former President John Adams in 1806, "whether any man in the world has had more influence on its inhabitants or affairs for the last thirty years than Thomas Paine."

Paine's opinions and personality aroused strong feelings in others. Some admired him greatly, but others hated him fiercely. Many historians regard Paine as a patriot who did much for America and asked nothing in return. He stated clearly and concisely political ideas that others accepted and supported, if necessary, to the point of death. Yet Paine died a social outcast.

Early life. Paine was born in Thetford, England. His family was poor, and he got little schooling. He began working at the age of 13. At 19, he went to sea. Later, he served as a customs collector in London, but was discharged. His first wife died, and he was separated legally from his second wife. Paine was alone and poor in 1774. But he gained the friendship of Benjamin Franklin, then in London, who advised him to go to America.

American revolutionary. Paine arrived in America with letters of recommendation from Franklin. Paine soon became contributing editor to the *Pennsylvania Magazine,* and he began working for the cause of independence. In 1776, he published his pamphlet *Common Sense,* a brilliant statement of the colonists' cause. This pamphlet demanded complete independence from Britain and the establishment of a strong federal union. It also contained a brilliant attack on the idea of monarchy and inherited privilege. Paine asserted that the Revolutionary War would begin a new era in world history. "The birthday of a new world is at hand," he wrote. George Washington, Thomas Jefferson, and other colonial leaders read it with approval, as did hundreds of thousands of ordinary Americans. *Common Sense* became the most widely circulated pamphlet in American history to that time.

In December 1776, Paine followed *Common Sense* with a series of pamphlets called *The American Crisis.* The first of these pamphlets began, "These are the times that try men's souls. The summer soldier and the sunshine patriot will, in this crisis, shrink from the service of their country. ... Tyranny, like hell, is not easily conquered." Washington had the pamphlet read aloud to his soldiers. Paine's bold, clear words encouraged the Continental Army during the darkest days of the war.

Paine served as a soldier in 1776. He also worked with a group of Pennsylvanians to create a democratic constitution for the state. In April 1777, he became secretary to the Congressional Committee of Foreign Affairs. His honesty in exposing questionable actions by Silas Deane, American commissioner to France, made him enemies, and Paine was forced to resign his position.

French revolutionary. Paine went to France in 1787 and then to England. While in England in 1791 and 1792, he published his famous *Rights of Man,* replying to Edmund Burke's attack on the French Revolution (see **Burke, Edmund**). William Pitt's government suppressed this work, and Paine was tried for treason and outlawed in December 1792. But he had returned to France.

The National Assembly of France made Paine a French citizen on Aug. 26, 1792. Paine became a member of

the National Convention. But his friends, members called the Girondists, lost power in the Convention. Then he was expelled from the Convention, deprived of his French citizenship, and imprisoned for more than 10 months (see **Girondists**). The American minister, James Monroe, claimed him as an American citizen and obtained his release.

While in prison, Paine worked on *Age of Reason*. It stated his views on religion, and many people called it the "atheist's bible." It began: "I believe in one God, and no more; and I hope for happiness beyond this life." Although Paine believed in God, he disagreed with many accepted church teachings and saw the established churches of Europe as obstacles to social change. His unorthodox views on religion made him one of the most hated men of his time.

Dies neglected. In 1802, President Thomas Jefferson arranged for Paine's return to the United States. Paine found that people remembered him more for his opinions on religion than for his Revolutionary War services. During his last years, Paine was poor, ill, and a social outcast. He was buried on his farm in New Rochelle, but 10 years later his body was removed to England. The location of his grave is unknown. Eric Foner

Paint is a substance that colors and protects a wide variety of surfaces. It is used on the inside and outside walls of buildings, on automobiles, on furniture and household appliances, and on many machines and machine parts. Most paints go on as liquids and then dry to form a thin solid film. A typical coat of paint is about 3\1,000 inch (0.08 millimeter) thick.

Paint consists of one or more finely ground *pigments* and a liquid *vehicle*. Pigments determine the color of the paint and provide it with certain other properties. Pigments commonly used for their color include titanium dioxide (white), iron oxide (yellow or red), phthalocyanine (blue or green), and toluidine (bright red). Manufacturers often add clay, mica, and talc to paint to increase its resistance to wear. These semitransparent materials are called *extenders* or *inert pigments*. Such pigments as zinc phosphate and barium metaborate help paint protect metal surfaces against rust. Pigments composed of fine metal powders give surfaces a metallic finish.

A paint's vehicle carries the pigment and binds it to a surface. Paint vehicles are composed of one or more *resins* and a *solvent*. Resins are sticky substances obtained from plants or manufactured through chemical processes. They are the main ingredient in paint. People often refer to paints by their resin type. Resins include acrylics, alkyds, epoxies, and polyurethanes. Resins largely determine the adhesive quality, drying time, gloss, and hardness of paints. Most are nearly colorless.

The solvent is the ingredient that makes paint a liquid. The solvent depends on the resins used. Most household paints, and an increasing number of industrial paints, use water as a solvent. Other commonly used solvents include mineral spirits, ketones, glycol ethers, and xylene. Solvents are sometimes called *paint thinners*. Vapors given off by some solvents can threaten a user's health, contribute to air pollution, and even play a part in the thinning of the protective layer of ozone in the upper atmosphere. The governments of many countries regulate the use of solvents in paints.

Kinds of paint

There are many kinds of paint. Chemists often classify paints according to the way they *cure* (dry and harden). For example, some paints cure simply through the evaporation of the solvent, which is accompanied by the hardening of the resin. Others form a solid film only after a chemical called a *catalyst* has triggered a reaction to bond the resin particles together. This reaction follows the evaporation of most of the solvent.

Paints are also grouped according to their use. For example, *household paints* decorate and protect houses, office buildings, and other structures. *Industrial paints* are used on a wide variety of consumer products and industrial equipment.

Household paints include paints for the walls, ceilings, floors, and exteriors of buildings. They are sometimes called *architectural paints*.

Most household paints are latex paints. *Latex* (natural rubber) was *emulsified* (evenly distributed) and used as the resin in early *water-based paints*—that is, paints that use water as a solvent. Polyvinyl acetate or acrylic resins have replaced latex in such paints, but these coverings continue to be called latex paints. Latex paints cure by *coalescence*. In this process, the resin molecules bond together to form a dry paint film. This bonding occurs as the water evaporates from the painted surface.

Latex paints are not flammable and have little odor. They dry to a film that can be easily cleaned with soap and water. Interior latex wall paints can tolerate repeated washings, but they are not durable enough for surfaces exposed to the weather. Sunlight can fade paint. Wind, rain, and extremely hot or cold temperatures can cause paint to crack, chip, blister, and peel. As a result,

PPG Industries

A rustproof coating is applied to a new automobile by submerging the car body in a tank of primer for three minutes. An industrial paint later will be baked on over this primer.

exterior house paints have been developed with resins that provide increased resistance to weathering.

Most exterior house paints are latex paints. But some are *oil-based*—that is, they contain resins and solvents obtained from petroleum products, vegetable oils, or linseed or other seed oils. Oil-based paints cure by *oxidation.* After most of the solvent has evaporated, the resins combine chemically with oxygen in the air to form a hard film.

Special paints called *primers, sealers,* or *undercoaters* are used when painting such porous surfaces as bare wood or plaster. Primers are applied as the first coat to form a smooth base for the final coat of paint.

The United States government restricts the content of lead pigments in household paint to 0.06 percent by weight of the dried film. This restriction was first applied in 1977, after the discovery that some children had developed lead poisoning after being exposed to paint with a high lead content. The affected children ate chips of dried paint with a high lead content, or swallowed or inhaled dust containing particles of this paint.

Industrial paints are used on such consumer products as automobiles, furniture, and household appliances. They also include coatings that protect machinery and other industrial equipment against moisture, strong chemicals, rust, and extremely high temperatures.

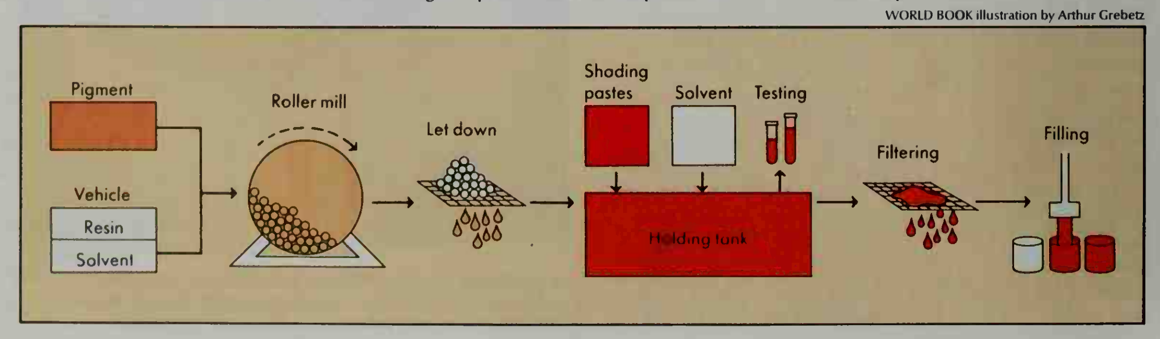
Most automobile manufacturers paint their cars with highly specialized coatings that contain acrylic resins and cure when they are baked on. Many kitchen and laundry appliances also have baked-on finishes. Such coatings produce an extremely hard surface that is resistant to harsh chemicals and does not dull or fade easily.

Manufacturers of wooden furniture often use wood stains on their products. The pigments in wood stains are highly transparent. They are dissolved in a vehicle that enables the stain to soak into the wood rather than stick to its surface as a film. Stains darken the color of wood but allow the wood grain to show through. After staining wood, manufacturers apply a clear, protective finish, often using lacquer or shellac. These finishes cure by *solvent evaporation*—that is, the resins solidify into a hard coat as the solvent evaporates. These finishes dry quickly and produce a shiny surface. After they have hardened, such finishes can be redissolved with the same solvents originally used in the vehicle. Manufacturers finish some wood products with varnish, a clear, oil-based coating that dries by oxidation.

Iron and steel may rust if they come in contact with moisture and oxygen. For this reason, manufacturers coat many products made of iron or steel with special rustproof primers and finish coats. Metal primers have high proportions of rust-resistant pigments. Some of these paints contain ingredients that penetrate rust to drive out oxygen and moisture. Finish coats cover the metal primer and seal it. In general, the primer protects the metal and the finish coat protects the primer. Manufacturers cover some metal products with enamels, which contain alkyd resins and dry by oxidation.

The most durable coatings available are generally used on machinery and other industrial equipment. They are often based on epoxy or polyurethane resins, which cure by chemical reaction. The chemical industry uses a number of such paints to protect the surfaces of pipes and containers that are used to store or carry harsh chemicals. Chemical companies have developed special heat-resistant coatings for high-speed aircraft, space vehicles, and equipment used in certain industrial processes. Some of these special paints can withstand temperatures as high as 1200 °F (650 °C).

How paint is made



All paints are manufactured according to a similar process. The basic steps of this process are (1) grinding, (2) let down, (3) shading, and (4) thinning.

Grinding. Batches of paint vary in size, but many batches are as large as 1,500 gallons (5,700 liters). To produce a batch of paint, manufacturers first load an appropriate amount of pigment, resin, and liquid chemicals into one of several types of grinding mills. The mill grinds the liquid and dry ingredients into a fine, uniform material called *mill paste.*

Manufacturers choose a mill according to the hardness of the pigments and the fineness of grind required for the paint. Latex house paints are usually prepared in a mill called a *high-speed disperser.* This mill has circular blades with saw-toothed edges. The blades rotate at high speeds, causing the pigment particles to collide with one another and break into smaller pieces.

How paint is made Paint is made by mixing colored pigment powder in a liquid *vehicle* that contains one or more resins and a solvent. The pigment and vehicle are made into a fine paste by the tumbling action of balls or pebbles in a ball mill. During *let down,* the paste is pumped from the mill and strained. In a holding tank, the color is adjusted by adding shading pastes, and the mixture is thinned with solvent. After final testing, the paint is filtered and poured into containers for shipment.

WORLD BOOK illustration by Arthur Grebetz

Other mills have a large, rotating steel cylinder partly filled with pellets or particles called *grinding media. Ball mills* contain steel balls that measure about $\frac{5}{8}$ inch (1.6 centimeters) in diameter. *Pebble mills* contain flattened ceramic balls about 1 $\frac{3}{8}$ inches (3.5 centimeters) in diameter. As the mill turns, the grinding media tumble against one another, crushing the pigment between them. Most of these mills rotate at about 16 revolutions per minute. The grinding process may last 24 hours.

Sand mills or *bead mills* can produce fine grinds faster than other mills. These mills shoot tiny glass beads through the pigment at high speeds. The mills can supply finely ground paste continuously or in batches.

Let down. After grinding the pigment, the paint maker adds more resin to the paste in the mill, along with a small amount of solvent. The paste is then "let down"—that is, it is pumped out of the mill through a strainer to a holding tank. The strainer removes the grinding media or other foreign matter from the paste. Workers rinse the mill with more solvent, which is then mixed with the rest of the material in the holding tank.

Shading, also called *tinting,* probably requires more care than any other step in the manufacturing process. In this step, paint producers compare samples of the material in the holding tank with color standards they keep on file. They then add small amounts of *shading paste* to the batch to adjust its color to the standard. Shading pastes are highly concentrated blends of ground pigments and a vehicle.

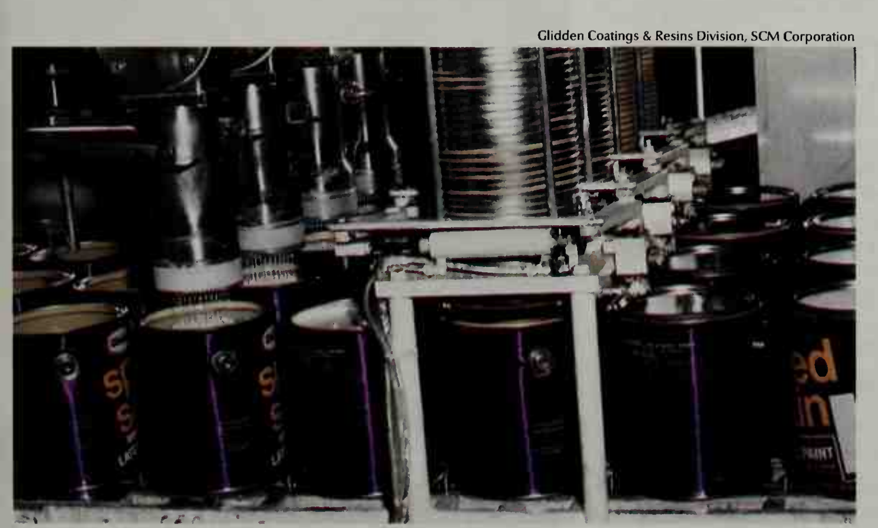
Thinning. After the batch has been shaded to specification, the paint maker thins it to the desired *viscosity* (thickness) by carefully adding solvent to it. Manufacturers then test the final product for quality. Finally, they filter the paint and pour it into containers for shipment.

How to use household paint

Selecting the paint. Household paint comes in flat, semigloss, and gloss finishes, and in a wide variety of colors. The nature of the surface to be covered plays an important role in choosing the finish and color of paint. For example, a single coat of paint is often sufficient when covering a similar color. But two or more coats may be required when painting over a different color. Flat paints, also called *dull* or *matte* paints, help hide flaws on surfaces. Gloss finishes, on the other hand, are smooth and shiny, and they readily show any surface defects. However, gloss paints are more durable than flat paints. Paints with intermediate levels of gloss are often called *eggshell, satin,* or *velvet.*

Preparing the surface. Poor surface preparation is the most common cause of paint failure. For paint to stick properly, the surface to be painted must be free of dirt, dust, grease, loose paint, moisture, oil, and wax. Often, washing a surface with soap and water is sufficient. But some surfaces may require scraping, brushing with a wire brush, or sanding. Others may also have cracks or holes that should be filled and sealed.

Stirring and filtering. Paint often settles. Always stir paint before applying it to ensure that it has a uniform consistency. One of the best methods is to stir in a figure-eight motion with a paint paddle. Lift the paddle occasionally to raise heavy pigments from the bottom of the can. Before painting, many people strain paint through a special paint filter, a fine screen, or a nylon stocking. This procedure is especially helpful when using old or leftover paint, which might contain dirt, rust from the can, or pieces of dried paint film.



Applying the paint. Paint may be applied with brushes, spray equipment, rollers, or paint pads. Small objects and irregular surfaces can best be painted with brushes or sprayers. Large, flat surfaces can be painted faster with sprayers, rollers, or paint pads.

Brushes are made of hog bristles or synthetic fibers. Hog-bristle brushes are used to apply oil-based paints. Synthetic-fiber brushes may be used to apply either oil-based or latex paints. To prevent streaking, spread the paint on a dry area and then brush it toward the wet edge of a previously painted area.

Spray painting produces a smooth coat of paint. Spray-painting equipment causes thinned paint to form droplets under pressure. When spraying paint, wear filter masks to avoid inhaling paint mist and vapor. Cover all surfaces that are not to be painted to protect them from the fine spray.

Rollers hold paint in fibers, the length of which determines the *nap* of the applicators. Rollers with short naps

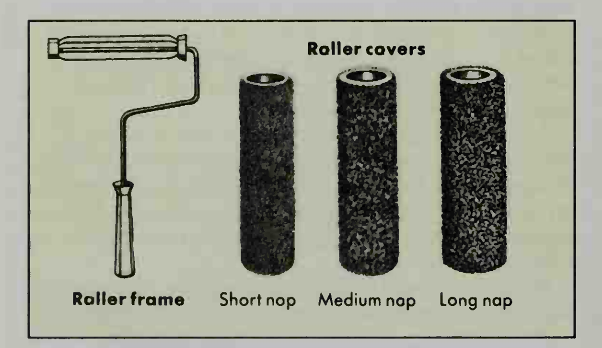
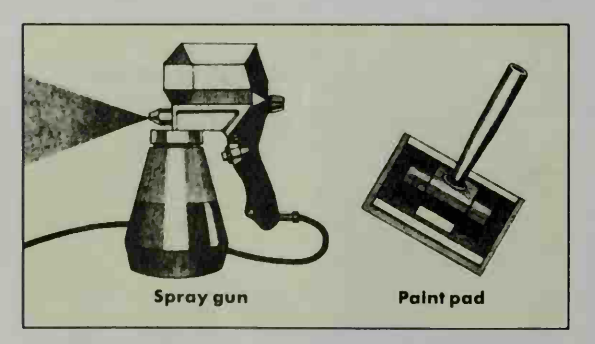
are suitable for applying thin paints on smooth surfaces. Long-napped rollers work better for thicker paints and textured surfaces. To produce an even coat, roll paint onto the surface in crisscross and up-and-down strokes. Each rolled strip of paint should overlap the wet edge of the previously painted area to avoid streaks.

Paint pads are made of foam, mohair, or synthetic fibers. They hold a large amount of paint and apply smooth coats of paint.



Types of paint applicators

Paint may be applied with brushes, rollers, spray guns, or pads. The choice of which type of applicator to use depends on the size, shape, and texture of the surface to be painted.



WORLD BOOK illustrations by David Cunningham

Paint brushes are especially good for painting small objects or irregular surfaces. Narrow sash brushes can reach into tight corners. Wider brushes are used for broad areas, such as walls.

Paint rollers paint large, flat surfaces quickly. Roller covers that have short fibers, or a short *nap,* are good for painting smooth surfaces. Covers with a longer nap are used for rough surfaces.

Spray guns and paint pads allow quick coverage of large areas. In addition aerosol spray cans easily paint small objects and irregular surfaces.

The history of paint

Prehistoric people made paints by mixing vegetable and earth pigments with water or animal fat. They painted on cave walls, on tombs, and on their bodies. Some caves in western Europe have walls that were painted about 30,000 years ago.

By 2000 B.C., the Egyptians painted tombs with materials similar to paints made today. These paints were made of crudely refined pigments, natural resins, and drying oils. The Egyptians imported pigments from as far away as India. By 1500 B.C., painting and paint making had become known in Crete and Greece.

The Romans learned how to make paints from the Egyptians. After the fall of the Roman Empire in the A.D. 400's, paint making became a lost art until the English began making paints near the end of the Middle Ages. They used paints chiefly on churches at first, and later on public buildings and the homes of wealthy people.

During the 1400's and 1500's, Italian artists and craftworkers developed their own paint-making processes. Unfortunately, they kept their formulas secret, and so the process of making a particular paint often died with its inventor.

The commercial manufacture of paints began in Europe and the United States during the 1700's. The early manufacturers of paint ground their pigments on a stone table with a round stone. The American colonists made their own paints using such materials as eggs, coffee grounds, and skim milk. They thinned these paints with water. In the late 1800's, grinding and mixing machines were developed that enabled manufacturers to produce large volumes of paint.

Improvements in paint technology closely paralleled advances in chemistry during the 1900's. Chemical companies developed many synthetic resins and a number of new pigments. Paints became increasingly specialized to meet the specific demands of industry.

tle Colorado River in north-central Arizona. For location, see **Arizona** (physical map).

The desert received its name from early Spanish explorers, who called it *El Desierto Pintado,* meaning *The Painted Desert.* It is a fantastic wasteland, with buttes, mesas, pinnacles, and valleys formed by ages of wind and rain cutting into shalelike volcanic ash. The pastel colors of the desert add to its beauty, especially because heat, light, and dust often seem to change the colors from blue, amethyst, and yellow to russet, lilac, and red. The Painted Desert is particularly beautiful at sunrise and sunset, when the colors are the most brilliant and the shadows the deepest. The bright reds and yellows of the desert come from iron oxides—hematite (red) and limonite (yellow).

The painted-tongue has trumpet-shaped blossoms with velvety looking petals. These blossoms have a wide range of colors and have made the painted-tongue a favorite garden flower.

Painted-tongue is a garden plant with large, trumpet-shaped blossoms. The blossoms, which resemble those of the petunia, have a wide range of colors, including deep red, pink, purple, brownish orange, salmon, yellow, and white. The petals have a rich velvety sheen and are often streaked with yellow and other colors. The painted-tongue has long, narrow leaves. It grows about 18 inches (46 centimeters) high and has several flowers near the top of each stalk. Native to Chile, the plant grows well in cool climates. It must be planted from seed each year.

Scientific classification. The painted-tongue belongs to the nightshade family, Solanaceae. Its scientific name is *Salpiglossis sinuata.* William G. D'Arcy

Painter refers to the artist who paints pictures, and also to the skilled worker in the building trades. Painters on construction projects work on both the outside and the inside of a structure. There are other opportunities for the skilled painter. A person with a talent for color and design may become an interior designer. Many painters go into business for themselves.

For biographies of artists who are painters, see the *Related articles* at the end of the **Painting** article.

Painter's colic, sometimes called *lead colic,* is a severe pain in the abdomen that results from lead poisoning. The pain is often accompanied by constipation or vomiting. Lead in paint can enter the body through the skin, or children may swallow lead paint that peels from walls. Lead vapors also may be inhaled. Scientists do not know why lead poisoning causes abdominal pain. See also **Lead poisoning.** James L. Franklin

Painting

Painting is one of the oldest and most important arts. Since prehistoric times, artists have arranged colors on surfaces in ways that express their ideas about people, the world, and religion. The paintings that artists create have great value for humanity. They provide people with both pleasure and information.

Sometimes artists paint primarily for their own enjoyment or self-expression, choosing their own subjects. Artists may also paint for a supporter called a *patron,* who *commissions* (orders and pays for) a work. A patron may be a private individual or a ruler who wants to decorate a palace or give the painting as a gift. A patron also may be an organization or institution. Religious groups have commissioned works of art to help believers worship and understand their faith. Rulers use art to assert their importance. Governments use painting to teach people about the history and ideals of their country.

Even when artists paint primarily for themselves, they want others to see their work and understand and enjoy it. People enjoy paintings for a number of reasons. Many viewers take pleasure in the artistic qualities of a painting, such as its colors or composition. Some paintings interest viewers because of the way the artists have expressed some emotion, such as fear, grief, happiness, love, hero worship, or faith. Such paintings, in turn, can inspire similar emotions in people looking at them. Other paintings are enjoyable because they skillfully portray nature or illustrate the daily lives of people who lived long ago.

Paintings can also teach. Some paintings reveal what the artists, their patrons, or their society felt about important subjects, including death, love, religion, and social justice. Many paintings tell about the history of the period in which they were created. They provide information about the customs, ideals, and interests of people of past societies. Much of our knowledge about prehistoric and ancient times comes from paintings and other works of art because many early cultures left few or no written records. For example, paintings can tell about such things as the architecture, clothing, recreation, and tools of a particular society or historical period.

What painters paint

It would be very difficult to find a subject that no one has ever tried to paint. Artists paint the things they see around them—people, animals, nature, and objects. They also paint dreamlike scenes that exist only in the imagination. An artist can reach back into the past and paint a historical event, a religious story, or a myth. Some artists paint pictures that show no recognizable subject matter at all. Instead, they arrange the paint in some way that expresses feelings or ideas that are important to them.

Famous artists and their paintings

The paintings reproduced in this article are listed below. These pictures were selected to represent the most important periods and styles in the history of painting. Each reproduction is accompanied by the following information, when available: the year the painting was finished, the medium in which it was created, its size, and its present location.

Painter, painting, and page number

placed side by side. Seen from a distance, the dots are meant to blend in the viewer's eye. In this painting, Seurat was really expressing his belief in new theories about color vision that were being advanced during his lifetime.

Since prehistoric times, many artists have painted the subjects that were most important to their societies. For example, religion was particularly important in Europe during the Middle Ages, and most of the paintings created then had religious themes.

All great paintings, regardless of subject matter, share a common feature. They do more than just reproduce with paint something that exists, existed, or can be imagined. They also express the painter's special view about a subject.

People have always been a favorite subject of painters. A portrait may show an individual or a group of people, or it may be a self-portrait of the artist. The people may appear alone, in religious or historical scenes, or in *genre paintings* (scenes of everyday life). The presence of people in a portrait can establish a bond between the viewer and the picture. The viewer can be drawn into the painting by eye contact with the subject or out of sympathy, amusement, or even adoration if the painting portrays a hero or religious figure. The English artist Thomas Gainsborough painted a double portrait called *Mr. and Mrs. Andrews* (page 32). The open, friendly gaze of the subjects invites the viewer into the world of their English country estate.

The French artist Honoré Daumier used people for an entirely different reason in *The Uprising* (this page). Daumier's people are taking part in the Revolutions of 1848, a series of revolts by the lower classes in Europe. Daumier was not interested in showing details of his subjects' clothing or surroundings. Instead, he crowded the people together in a scene that suggests action. He made the people seem more like symbols of the revolutionary spirit than like real human beings.

The two people in Austrian artist Oskar Kokoschka's *The Tempest* (this page) are caught up in a mysterious swirling scene that cannot be explained in a logical way.

The artist painted the people in this way to show how powerful emotions apparently swept the couple away from the activities of everyday life.

The treatment of people in painting can range from extremely realistic to nearly *abstract,* a style that emphasizes shapes, colors, and patterns instead of recognizable subject matter. The American artist Chuck Close's lifelike *Big Self-Portrait* (page 34) was created with the help of photographs. It realistically emphasizes every feature of the artist's unshaven face, demanding our attention by its huge scale. In contrast, the American artist Willem de Kooning painted *Woman, I* (page 85) in an almost abstract style to create a savage vision of the subject.

Religious subjects dominated painting in some parts of the world for hundreds of years. A large number of all the pictures ever painted in Asia are religious. European painters of the Middle Ages and the Renaissance painted more religious pictures than any other kind.

Paintings have played an important part in religious rituals and worship. These paintings have taken a number of forms, including altarpieces and illustrations in prayer books and books of psalms. Worshipers have carried some paintings that they considered especially holy in religious processions.

Paintings have honored deities and saints and also encouraged religious feeling, which could be expressed as adoration, sorrow, joy, or horror. The Flemish painter Jan van Eyck's *The Madonna and Child with Chancellor Rolin* shows the chancellor praying in his room. As he looks up, he sees the Virgin Mary and the infant Jesus before him. This painting appears in the **Renaissance** article.

Paintings can also portray the lives of gods and holy people. Many paintings commemorate the birth, ministry, Crucifixion, and Resurrection of Jesus Christ. Examples appear in the **Jesus Christ** article. Religious paintings can also teach moral lessons. Michelangelo's *The Last Judgment* shows the eternal happiness that rewards the faithful and the horrors of hell that will be the punishment of sinners. This painting appears in the **Religion** article.

light and space on a clear, calm morning on the New England seacoast in *Owl's Head, Penobscot Bay, Maine* (page 32).

Landscapes and seascapes also reflect the importance of land ownership and seafaring. In Gainsborough's *Mr. and Mrs. Andrews,* the country estate takes up more space than the human figures, symbolizing the importance of the land to the couple. In the Netherlands during the 1600's, seascapes were popular subjects because much of the country's wealth and power depended on sea trade.

Chinese artists portrayed the beauty of mountains in landscapes painted in ink on paper or silk and mounted on scrolls. An example is *Travelers Among Mountains and Streams* (page 34) by Fan Kuan. The artist intended viewers to journey slowly through the painting with their eyes. Wandering through the picture, viewers closely observe its mountain formations, waterfall, trees, village, and tiny figures of travelers. In Japan, makers of an early type of kimono called the *kosode* sometimes painted landscapes on the garments, such as *Kosode with Plum Tree and Flowering Plants* (this page) by Sakai Hoitsu.

Sometimes artists used landscape paintings as extensions of real nature. Many Roman gardens had landscapes painted on their walls to extend the real garden by means of make-believe.

Still-life paintings are close-ups of objects. The objects can be natural, such as fruits and vegetables, or manufactured, such as bottles and rifles. Many still lifes express the bounty of nature and the harvest, or the wealth of patrons or the artist's society. In the 1600's, European painters often showed fish shops and vegetable stalls overflowing with goods. In the Netherlands during that time, some still-life artists painted arrangements of food called *breakfast pieces.* An example is *Breakfast Table* (page 64) by Willem Claesz Heda.

Some artists have painted precise, minutely realistic still lifes called *trompe-l'oeil (fool the eye).* Some artists have made formal, almost abstract compositions of still lifes. One example of this is *The Bottle of Banyuls* by Spanish artist Juan Gris. This painting appears in the **Cubism** article.

Because flowers and fruits eventually wither and die, artists have sometimes used them to express the passing of time and the decay of matter. In this way, the paintings remind viewers of their own aging and future death.

History paintings show important events from the artist's own times or from the past. Such paintings can portray significant occasions in a nation's history. John Trumbull painted *The Declaration of Independence* only a few years after this event took place. The artist actually knew many of the signers. This painting appears in the **Declaration of Independence** article.

Often a ruler commissions a painting to glorify himself or herself as well as the country. Napoleon I of France made Jacques Louis David his official painter to glorify his reign.

Scenes from Greek and Roman history were popular in European painting because the Europeans considered ancient Greece and Rome the ancestors of their civilization. Sometimes, artists used subjects from ancient times to make a moral or patriotic statement ad-

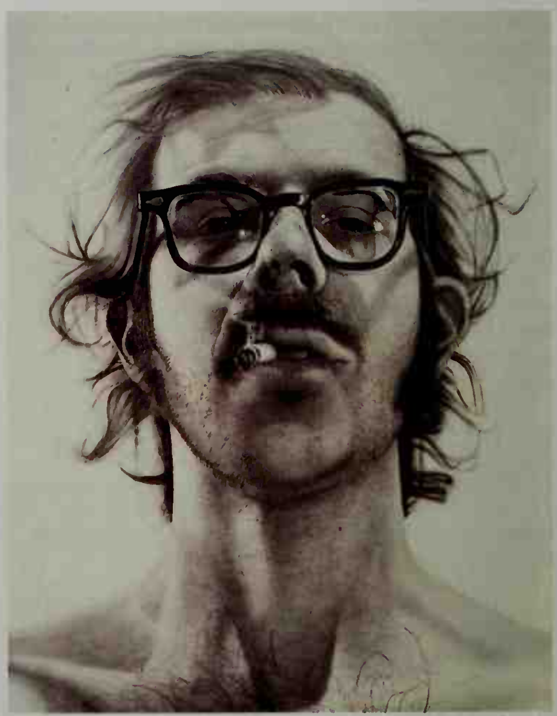
dressed to the viewers of their own day. An example is David's *The Oath of the Horatii* (page 67). The painting portrays three brothers vowing to their father to fight for the Roman Republic, even though their decision will bring sorrow to their families. The artist is telling the viewer that public duty, self-sacrifice, and patriotism are more important than an individual's or a family's personal interests, safety, or happiness.

Mythology paintings tell stories of gods and goddesses. For example, an ancient Greek artist known only as the Dinos Painter painted a mythological scene on a *dinos,* a large bowl for holding wine (page 33). The god Triptolemos, in the center, is about to depart in his winged chariot drawn by a snake to teach humanity how to cultivate grain. He and the goddess Demeter hold stalks of wheat. At the right, Demeter's daughter Persephone offers a bowl of wine in honor of the god's departure.

Social expression has been a common theme throughout art history. Many artists have painted pictures that express political beliefs or attack social ills, such as war and poverty. The Spanish artist Francisco Goya protested the cruelties of war in such works as *The Executions of 3rd May, 1808* (page 68). The painting shows civilians being executed by a military firing squad.

Decoration has been an application of painting since prehistoric times. Almost all ancient Greek paintings that survive are those that decorate pots, vases, and other ceramics. For centuries, people have hung paintings on the walls of homes as decoration. Wallpaintings decorated the interiors of many palaces and public buildings during the Renaissance in Italy. For an example by the Italian artist Andrea Mantegna, see the **Fresco** article.

Abstract painting deliberately omits recognizable subject matter. Instead, the artist explores form, color, design, pattern, and texture. Some abstract paintings still express a meaning, even without identifiable subject matter. The American artist Robert Motherwell painted *Elegy to the Spanish Republic LV.* The abstract painting is one of a series that expresses the artist's sorrow over the Spanish Civil War (1936-1939). It appears in the article **Motherwell, Robert.** Many abstract paintings, on the other hand, have no meaning. An abstract picture called *Mountains and Sea* (page 29) by the American artist Helen Frankenthaler has no significance other than the artist's interest in color and texture.



The elements of painting

Paintings consist of many artistic elements. The most important elements are (1) color, (2) line, (3) mass, (4) space, (5) texture, (6) composition, and (7) light and shade. These artistic elements are as important to a painter as words are to an author. By stressing certain

elements, a painter can make a picture easier to understand or bring out some particular mood or theme. For example, an artist can combine certain colors and lines in a painting to produce intense excitement. The same artistic elements can also be combined in a different way to create a feeling of peace and relaxation.

Color is one of the most versatile elements of painting. The Spanish artist Pablo Picasso and the French artist Raoul Dufy used blues to create contrasting moods. Picasso evoked a sense of sadness and loneliness in *The Old Guitarist,* which appears in the **Color** article. Dufy produced a cheerful, airy scene in *Le Haras du Pin,* which appears in the article **Dufy, Raoul.**

Line is one way in which artists build up forms in their paintings. Line also defines space and creates *perspective,* the illusion of depth and distance. Some paintings, such as Chinese landscapes, are composed almost entirely of lines. The Dutch artist Piet Mondrian used lines to define shapes in such abstract paintings as *Composition* (page 80).

Mass allows an artist to express the feeling of weight in a painting. Mass helps the viewers believe they are looking at three-dimensional objects even though the picture is two-dimensional. The German-born artist Richard Lindner created a sense of power and threatening strength by painting the female figure in *Disneyland* with a massive lower body. This painting appears in the article **Lindner, Richard.**

Space is the arrangement of lines and colors to create the impression that the flat surface of a painting is actually a window into a three-dimensional world. An emphasis on empty space in a painting can carry emotional meanings. The American painter Andrew Wyeth created a sense of loneliness and abandonment through the skillful rendering of space in *Teel's Island.* This painting appears in the article **Wyeth, Andrew.**

A painting with a restricted amount of space can establish a closed-in feeling. The Italian artist Jacopo Pontormo created a dramatic, uneasy feeling through the use of confined, distorted space in *Supper at Emmaus.* This painting appears in the **Mannerism** article.

Texture refers to the appearance of the painting's surface. The paint may be thin and smooth or thick and rough. The Dutch artist Vincent van Gogh painted *The Starry Night* (page 39) with thick, swirling brushstrokes to portray a sensation of excitement and agitation.

Composition refers to how elements are arranged in the painting. The artist can choose to compose a flat abstract painting, such as Robert Motherwell's *Elegy to the Spanish Republic LV,* or the artist can create three-dimensional space, as in *Las Meninas* (page 65) by the Spanish painter Diego Velázquez. Composition determines how the painter wants a viewer to "read" a painting. Sometimes the composition emphasizes the most important people or elements by putting them front and center or on a larger scale. The Italian artist Piero della Francesca directed the viewer's attention to the risen Jesus Christ by placing Jesus at the top of a pyramid-shaped composition framed by trees. This painting of the Resurrection appears in the **Easter** article. On the other hand, a painting may be composed to allow the viewer's eye to wander through the picture, as in a Chinese landscape.

Composition can contribute to the mood of a painting. The Canadian artist J. E. H. MacDonald composed his landscape *The Elements* to evoke a feeling of nervous intensity. This painting appears in the **Group of Seven** article. In contrast, the French artist Claude created a feeling of calm order in his landscape *The Father of Psyche Sacrificing at the Temple of Apollo.* This painting appears in the **Classicism** article.

Light and shade can be used to define form and mass, to direct the eye within the composition, to create space, and to change colors. The French artist Claude Monet created a series of paintings of Rouen Cathedral in France. In this series, the angle and intensity of the light at different times of day determine how the viewer sees the architectural forms of the cathedral. One of these paintings appears on this page.

The Dutch painter Rembrandt skillfully used bright light and deep shadow to establish a tragic mood in *The Descent from the Cross,* which appears in the **Rembrandt** article. Light or its absence can have a symbolic meaning. In *The Oregon Trail* by the American painter Albert Bierstadt, a wagon train travels into a brilliant afternoon sun. The glowing light symbolizes hope for the pioneers. The painting appears in the **Pioneer life in America** article. In Motherwell's *Elegy to the Spanish Republic LV,* the darkness of the abstract forms symbolizes death, while the white background represents life.

Materials and techniques

From prehistoric times to the present day, the painting process has remained basically the same. Artists use powdered color called *pigment* combined with a *binder* that holds the particles of pigment together. The artist may thin the paint, usually with water or turpentine, so it can easily be applied with a brush or brushlike implement onto a *support*. The support is a surface that could range from a prehistoric cave wall to a modern piece of canvas.

The process of painting has not changed over time, but the materials and techniques have changed greatly. Today, artists have many more pigments available to them than they did in ancient times and a much wider variety of binders, thinners, brushes, and supports. Depending upon what choices the artists make among these materials, they can achieve an almost limitless variety of effects.

Pigments. Good painting pigment should be permanent. It must be capable of withstanding normal changes in atmospheric conditions, including light, temperature, and even pollution.

During the Renaissance of the 1400's and 1500's, Italian artists processed iron oxides to produce a range of red, yellow, and brown pigments. They also produced green pigment from copper dioxides. In the late 1800's, artificially produced pigments began to replace the less stable and increasingly rare natural colors. Today, synthetic pigments are the most common color elements in paint.

Binders protect the pigment from changes in atmospheric conditions and serve as an adhesive to anchor the paint to the support. Common binders include vegetable gum arabic and linseed oil.

Different binders have different characteristics. Some dry quickly and others more slowly. Some create an almost transparent paint, while others are *opaque*—that is, they cannot be seen through. The same pigment used in water color, for example, will look different in oil paint because the binder in each possesses different degrees of transparency.

Thinners reduce the *viscosity* (thickness) of a paint so the paint can be more easily applied to the support. Different binders require different thinners. Water is used to thin water color and paints made of synthetic resins. But because oil and water do not mix, water cannot thin oil paint. Instead, painters commonly use turpentine or mineral spirits.

Most thinners are flammable. Many are *toxic* (poisonous), capable of causing minor skin irritations or even permanent damage to the lungs, liver, heart, and brain. Painters should wear goggles and gloves when handling most thinners. Many artists use protective creams under their gloves. The use of thinners requires adequate ventilation. The studio must be cross-ventilated with a minimum of two open windows and an exhaust fan.

Supports. Almost any surface can serve as a support for a painting—a wall; a piece of bark; a panel of wood; or a sheet of fabric, paper, metal, or glass. For much of the history of painting, walls and ceilings were the primary supports. But such surfaces have a basic limitation. The painting, once in place, cannot be moved.

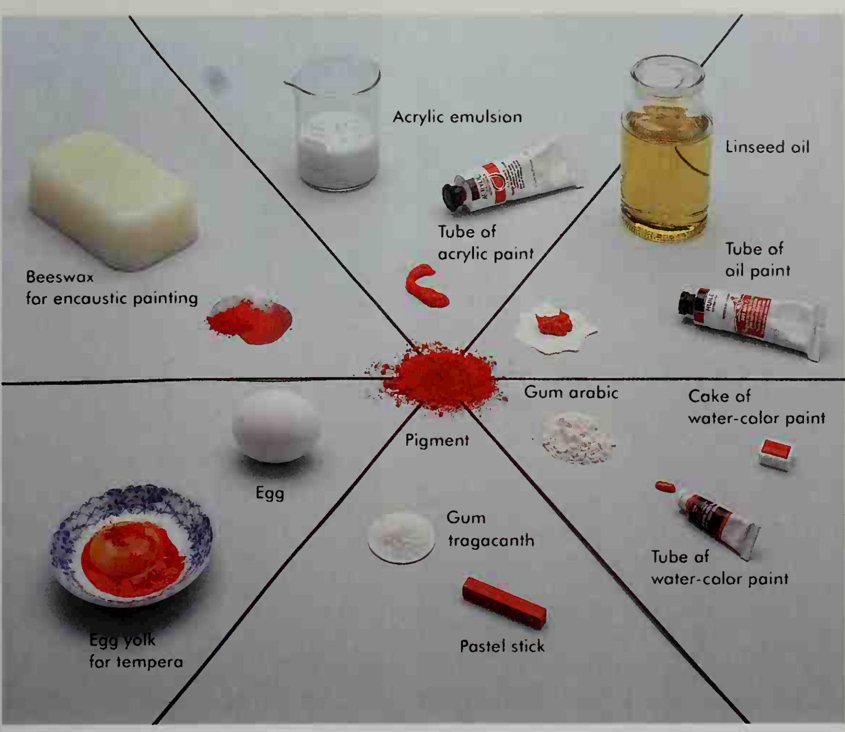
By the 1400's, artists began to paint on supports that were small, light, and portable. They first painted on lightweight wood panels, and later on canvas stretched tightly on a wooden frame. Paper also became an important support. The Chinese, who invented paper more than 2,000 years ago, first painted on it. The material became widely available in Europe in the late 1400's. Paper is fragile, but its porous character makes it the preferred support for water color.

Grounds. Most supports are too absorbent to allow the easy application of paint. Artists usually *prime* (pretreat) a support with one or more coats of a special paintlike material called a *ground*. The only exception is paper for water colors, because the paper's absorbency is right for the paint. Grounds also make the support surface smoother or more uniform in texture. Many grounds, especially white grounds, increase the brightness of the final picture. The three most common grounds are (1) *oil ground*, (2) *glue gesso*, and (3) *polymer gesso*.

Oil ground is made with white pigment, often white lead, in a binder of linseed oil thinned with a small amount of turpentine. After drying, normally in about three days, the oil ground is lightly sanded and a second coat is usually applied. White lead is toxic, so painters should use extreme caution in preparing white lead oil ground. Artists prefer oil ground when they paint on canvas.

Glue gesso is a mixture of white chalk and glue dissolved in hot water. It forms a brittle plasterlike surface that tends to be too stiff for canvas. Glue gesso is used most widely on wooden or wall board panels.

Since the mid-1900's, acrylic gesso has become increasingly popular. It provides a ground of brilliant white that retains flexibility. It does not, however, form a ground suitable for oil painting. Oil paint becomes increasingly brittle with age, while acrylic gesso retains its flexibility. If the two were used together on large oil paintings on fabric, the paint might separate from the ground.



Other materials. When painting with oils or oil-based paint on fabric, the artist must *size* the support before applying the ground. The *size* is a solution of glue, thin enough to penetrate the pores of the support and cover it with a continuous, even film. The size separates the canvas or paper from the oil to protect the support. If oil comes into direct contact with canvas or paper, the support will rot.

Artists apply paint with brushes and painting knives. Brushes come in many sizes and shapes. Bristle brushes are made from the hair running down the spine of a hog from neck to tail. Sable brushes are made from the hair of ermine, martens, and weasels.

Painting knives come in almost as many sizes and shapes as brushes. They are used particularly to apply paint in thick, bold strokes. Areas of thickly applied paint are called *impasto*.

The artist mixes paint on a palette. Almost any flat surface can serve as a palette. Traditionally, palettes have been made of wood, but glass palettes have become increasingly popular because they are easy to clean.

Encaustic painting is made by combining pigment with a hot wax binder—pure beeswax is preferred. Encaustic is one of the oldest techniques in painting. It was

widely used in ancient Greece, though few paintings from that period survive.

The encaustic process is demanding. The artist must work quickly, with short brushstrokes, because molten wax hardens soon after it is removed from heat. Colors are difficult to blend because one will have hardened as the other is prepared. However, some blending is accomplished in a *burning-in* process in which the painted surface is reheated. The brushstrokes can be blended at this point. The burning-in process also allows the wax to stick to its gesso ground.

Although encaustic was virtually abandoned for centuries, the invention of electric heating elements in the 1900's made the technique more practical. Modern painters can use an electric frying pan as a palette and a heat lamp for the burning-in.

Fresco painting is a wallpainting technique. The artist applies pigment to a lime plaster wall. When the paint, mixed with water, is applied to a freshly plastered wall, the process is called *buon fresco* (*good,* or *true, fresco*). When paint is applied to a dry wall that has been moistened, it is called *fresco secco* (*dry fresco*). In buon fresco, the fresh lime plaster absorbs the wet pigment, and the painting becomes part of the wall. In dry fresco, the damp plaster never blends with the paint, which has been mixed with binders such as casein, egg yolk, or glue. Over time, moisture can penetrate between the paint and the wall, causing the paint to crack and peel. See Fresco.

is then added equal to the amount of paste. The artist carefully applies the paint with the tip of a fine brush, preferably sable, to a smooth ground prepared with gesso. Tempera dries almost immediately into a water-resistant coating. Because the paint dries so quickly, colors cannot readily be blended. Effects of shading must be accomplished through short lines called *hatching.* The denser the lines, the darker the shaded areas will be.

Tempera painting uses fine, crisp brushstrokes that produce detailed images of extreme clarity and precision. The gesso used as a ground is fully absorbent. When it combines with the tempera, it creates a durable surface that seems to glow. Tempera painting was largely replaced in the 1500's by oil painting. However, several modern artists, including Ben Shahn and Andrew Wyeth, have adopted tempera to take advantage of its characteristic soft, warm light.

Oil painting. Unlike tempera, oil paint can be blended on the painting surface to create a continuous scale of tones and hues. Many shades, especially darker ones, were impossible before the invention of the technique. Using oil paint, the artist can render subtle changes in light and achieve realistic three-dimensional effects. Even more important for the artist, oil paint dries slowly, allowing the artist to work almost endlessly to perfect the image.

Oil paint is made by mixing powdered pigments with a binder of vegetable oil, usually linseed oil. The pigment can be thinned by adding a solvent, such as turpentine. This solution can make thin films of almost transparent color that glaze the painting's surface. The glazing lends a luminous sense of reality to the images.

In oil paint, artists are free to express their personalities through their brush marks. The trail of the brush's path across the painting surface is almost like the artist's autograph. This is especially true when the artist brushes new paint into the undried surface so that it mixes freely with what has previously been painted. The painter's emotions can be detected in the intensity of the brushwork.

Pastel is the painting technique closest to drawing. The artist uses a colored chalk pastel stick. Holding the stick like a pencil, the artist can work rapidly to create broad strokes of color or short, crisp lines.

Pastels are made of pigment held together by a weak, nonliquid adhesive binder such as gum tragacanth. Pastels are labeled *soft, medium,* or *hard,* depending upon how much adhesive is used. Because the pigment is diluted by increased quantities of adhesive, the harder the stick, the less intense its color. Artists seeking brighter colors must work with the fragile softer sticks. Because there is no liquid binder to hold the pigment to its ground, pastel colors rub off easily. To protect the colors, a solution of glue or resin called a *fixative* can be sprayed over the finished picture.

Water-color painting is made by applying pigments suspended in a solution of water and gum arabic to a ground of dampened paper. The paint is transparent. The more water added to the paint, the greater its transparency and the softer its tone. Water color readily spreads through the fibers of the paper, making the edges of the broad painted areas, called *washes,* characteristically soft and fluid. Harder and more precise lines can be achieved by applying relatively undiluted color with a pointed brush, or even by drawing on the

Synthetic resin painting is a popular technique for murals. The Mexican muralist David Siqueiros pioneered in the development of synthetic resin paints as he sought a durable, easily adaptable paint. His mural *From the Dictatorship of Porfirio Díaz to the Revolution, left,* is a notable example of the artist's experiments with modern synthetic materials.

painting with a pencil or with pen and ink.

Water color is one of the oldest painting techniques, used by ancient Egyptians to illustrate papyrus scrolls. However, artists did not begin to explore the expressive potential of the medium until the 1800's. Artists found that water-color equipment was light and easy to use outdoors, and the paintings dried quickly. As a result, the technique was especially suited to making quick, sketchlike studies of nature.

In one variety of water color, called *gouache,* white pigment or chalk is added. Gouache paintings are characterized by broad, flat areas of color.

Synthetic resins. Starting in the 1930's, painters began to experiment with binders made of synthetic resins. Mexican mural painters pioneered in the development of synthetic resin paints. Painting outdoors, the muralists worked first in fresco and then oil paint, but the sun, rain, and humidity of Mexico jeopardized their works. In 1936, muralist David Siqueiros organized a workshop in New York City specifically to experiment with synthetic paints. One of the first synthetic paints he used was pyroxylin, commonly known as Duco, a lacquer developed as an automobile paint.

By the mid-1950's, researchers in Mexico and the United States had developed a way to mix acrylic resins with water. An artist using acrylic paints can produce works that look almost identical to oil paints. Alternatively, by thinning the paint with water, the artist can create works that resemble water colors. Because there is no chemical reaction between an acrylic resin and its ground, artists can paint with acrylics on unprimed supports.

Acrylic paint can be used on almost any surface. It dries rapidly and is extremely durable. Painters seeking a longer drying time to simulate some of the effects of oil painting add *retarders* to the paint. But even then the paint normally dries within an hour. Because acrylic paints are water-based, they are far less toxic than oil paints and safer to use in closed environments.

Early painting

Prehistoric painting. The earliest paintings date from about 30,000 years ago, during the Paleolithic Period, also known as the Old Stone Age. Prehistoric paintings are found on the walls of caves primarily in France and Spain, but also in Italy and Portugal.

The earliest paintings show animals, human beings, and arrangements of lines and other abstract signs. The artists used earth pigments such as manganese and ochers for red, yellow, and brown; and charcoal for black. They drew directly onto the walls with lumps of these pigments; or they mixed finely ground pigments with water and daubed, brushed, or blew them on. By chance, the pigments, mixing with the moisture in the cave walls, bonded chemically with the limestone to produce the first frescoes.

The most common subjects of cave paintings are large animals—horses, cattle, bison, deer, and mammoths. Many paintings show close observation, with subtle shadings of color, producing a startling realism. Some of the most famous cave paintings were discovered in a cave in Lascaux, France (page 41). For other examples from Lascaux, see the **Horse** and **Prehistoric people** articles.

No one knows exactly why artists painted pictures on cave walls. Scholars agree, however, that cave paintings were not just decorative. Most paintings are in dark and nearly inaccessible parts of caves, difficult places to paint or see the pictures. The art may have served as magical aids in hunting or fertility, as part of initiation rites, or in other ways that were important to early peoples. Between about 8000 and 3000 B.C., during the Neolithic Period, or New Stone Age, artists painted pictures for the first time on the walls of religious chambers or shrines, and on objects, such as pottery.

Egyptian painting. Most Egyptian painting that survives comes from papyrus scrolls and the walls of tombs. The earliest paintings were simple designs, dat-

ing from about 3000 B.C. During the time of the Old Kingdom (2686 to 2181 B.C.), Egyptian artists normally carved scenes in low relief on tomb walls and then painted the reliefs. The scenes depicted Egyptian deities and daily life. The Egyptians believed these subjects were necessary to ease a person's journey to the land of the dead and to provide for that person in the afterlife.

From the Middle Kingdom (1991 to 1786 B.C.) through the New Kingdom (1570 to 1070 B.C.), artists covered the limestone walls of the tombs with a fine layer of plaster and painted the scenes of deities and daily life directly on the plaster. Painters used few colors, primarily black, red, yellow, brown, blue, and green. They mixed their colors in a binder to make them stick to the dry plaster. By applying the colors thinly or thickly, or by mixing them with black and white pigments, the Egyptian artist could achieve a great range of colors and values.

The Egyptians wanted their tombs and paintings to last for eternity, especially paintings of important people, such as nobles and pharaohs. Artists developed a highly stylized way of showing these important people. They showed each part of the body in its most recognizable form. For example, they drew faces, feet, and legs in profile. They showed the eyes, shoulders, and torso from the front.

Egyptian artists painted figures in flat colors without shading. They used dark red or brown for the flesh of men. They painted women's flesh in yellow, white, or pale brown. This style of coloring can be seen in the painting in the **Hieroglyphics** article.

Nobles and pharaohs sat stiffly or stood solidly on lines representing the ground. Egyptian artists often made members of the nobility larger than other figures in a scene to show their greater importance. The artists portrayed less important people, such as workers, servants, and enemies, in more natural poses and more comfortable movement. For examples, see **Agriculture; Paper; World, History of the** (Early centers of civilization).

The rigid style conventions of Egyptian painting relaxed slightly during the period of the New Kingdom, reflecting the influence of cultures that flourished on Crete and the nearby islands and shores of the Aegean Sea. An example is the more casual pose seen in the tomb painting *Fowling in the Marshes* (page 44). When Egypt came under Roman rule, starting in 31 B.C., portraits of the dead on mummy cases followed the style of Roman painting. Painters posed the bodies in three-quarter view, with the faces nearly frontal. The forms are subtly shaded, using fine strokes of dark and light. However, most tomb paintings from the period of Roman rule followed the style of the period of the Old, Middle, and New Kingdoms. For examples of ancient Egyptian painting, see **Egypt, Ancient** (pictures: Paintings inside tombs); **Heart; Mythology; Osiris.**

Aegean painting. The term *Aegean* is used for the civilization that flourished from about 3000 to 1200 B.C., during the Bronze Age in and near the country now called Greece. This civilization was made up of four cultures. The Minoans inhabited the island of Crete. The Cycladic people lived on islands in the Aegean Sea. The Mycenaean culture, also called the Helladic culture, developed on the Greek mainland. The Trojans lived in the city of Troy in what is now northwest Turkey. Most surviving Aegean painting comes from ceramic vessels and the walls and floors of palaces, villas, and shrines.

Aegean artists painted subjects from nature, including scenes of plants and animals of both land and sea. Many paintings add scenes of religious processions and festivals, along with images of goddesses. Mycenaean and Cycladic painting includes scenes that depict warfare.

The best Aegean wallpaintings come from the palace of Knossos on the island of Crete, but these paintings have survived only in fragments. The most complete Aegean paintings come from the Cycladic island of Thira (also spelled Thera). These paintings show scenes of festivals, animals, battles, sports, and religious ceremonies. One shows a landscape. Many scholars believe that all these paintings had religious significance. An example of a Thira wallpainting appears on page 42.

Aegean art emphasized some of the same conventions used in Egyptian art. For example, Aegean artists

normally painted faces in profile, with a frontal eye. They contrasted the skin of males and females by color. However, Aegean artists applied their colors more thinly and freely than Egyptian artists and more often painted on wet plaster in the true fresco technique. Figures painted by Aegean artists are also more active than Egyptian figures. They move comfortably and are often shown in profile. Figures painted life-sized usually stand close to the front of the picture and are set against a neutral background. However, other figures inhabit complex landscape and architectural settings. Aegean artists indicated distance by placing some figures and buildings higher on the wall.

Greek painting. The earliest Greek painting dates from the 1000's B.C. and is found on vases. Early painters preferred pure ornament, such as lines, circles, and other patterns. They drew figures in black silhouette but based the figures on geometric shapes. The period from about 900 to 700 B.C. is known today as the *geometric style.*

In the 600's B.C., vase painters created scenes from mythology as well as from everyday life. Artists still drew figures in black silhouette. But painters in the city of Corinth cut fine lines into the black silhouette to show detail, and artists in Athens often painted figures in outline to achieve more precise form. Basically, however, artists still showed figures in the old Egyptian style. They painted male figures black, but left female figures in the light color of the clay or painted them white.

About 625 B.C., artists in Athens adopted the *black-figure* technique invented in Corinth in the early 600's. In black-figure painting, the figures are painted in black silhouette. Artists cut details into the surface or added them in red and white. Athenian black-figure vases are the best examples of Greek painting of the 500's. The vases show scenes from Greek mythology as well as simple scenes of daily life that provide some of the most important visual documents of the time. *Achilles and Ajax Playing Checkers* (page 43) by Exekias is an example.

About 530 B.C., Athenian painters invented the *red-figure* style. In red-figure painting, the figures are left in the natural red color of the clay, and details are painted in black with a brush. The red-figure technique freed artists to experiment with a new realism. Almost immediately, artists began to depict figures twisting and turning in space. By the mid-400's B.C., artists were placing figures on different levels of the vase's surface to indicate relative distance. For examples of red-figure painting, see the *dinos* (page 33) and **Furies; Mythology** (Greek mythology); **Odyssey; Oedipus.**

The 400's and 300's marked the great age of Greek wallpainting, but none of these paintings has survived. Artists also painted simple scenes of figures on gravestones and more complex ones on the walls of monumental tombs, especially in the historical region of Macedonia in northern Greece. Superb paintings from the 300's decorated royal tombs in the ancient city of Vergina. The painter placed the action within a landscape setting. The figures are shaded, and almost all are shown in three-quarter view to emphasize the depth of the space in which they act. The artist placed some figures higher on the surface than others in order to further indicate depth.

Etruscan painting. By about 800 B.C., the Etruscans had settled in Etruria, a region in west-central Italy. They imported vases from Greece—especially from Athens—and followed Athenian models for their own black-figure and red-figure vases. The Etruscans also followed these models for the scenes they painted on the walls of their tombs. These tomb paintings show banquets, dancing, sports, and games. Some paintings depict the voyage of the dead to the afterlife. Although their paintings follow the Greek style, Etruscan artists expressed views of their own. They showed subjects, particularly demons, unique to their own religion. By the 200's B.C., some Etruscan tomb paintings showed events in the careers of the deceased, a subject never found in Greek painting. See **Rome, Ancient** (picture: The Etruscan culture).

Roman painting. By the late 100's B.C., Rome had conquered Etruria and Greece, incorporating both regions into the Roman Empire. From these conquered lands, Rome inherited traditions that formed the founda-

tion of its artistic style. The Greeks and Etruscans had limited large-scale painting to public buildings and tombs. However, the Romans used painting primarily to decorate the walls of their houses.

Roman painting is best known from the cities of Pompeii and Herculaneum. Both were buried and preserved by the volcanic eruption of Mount Vesuvius in A.D. 79. Additional Roman paintings have survived from the villas near the mountain. Based on the discoveries at Pompeii and Herculaneum, scholars have generally divided Roman painting into four *Pompeiian* styles based on the decorative scheme of the wallpaintings.

The first style (late 100's to 80 B.C.) featured modeled stucco in relief to imitate large, neatly cut stone blocks. Artists often painted these simulated blocks to imitate colorful marble or other costly stone.

The second style (80 to 15 B.C.) created the illusion of monumental architecture. Artists employed perspective, shading, and shadows to make paintings of columns and other architectural elements that fool the eye with their realism.

The third style (15 B.C. to A.D. 63) rejected the illusion of depth. Instead, artists painted the walls as solid surfaces enlivened with delicate decorative detail.

The fourth style (A.D. 63 to 79) is the best-preserved style. It mixes features of the second and third styles in its real-looking architecture combined with solid areas, rich colors, and decorative detail. An example is *Landscape with Polyphemus and Galatea* (this page) from a villa near Pompeii that was buried in the Vesuvius eruption.

From the second style onward, walls in Roman houses became picture galleries displaying the strong influence of Greek master paintings. In the second style, the wall became the picture itself. In the third and fourth styles, artists painted panels that seem to hang on the walls. Many of these paintings illustrated Greek myths. Others were still lifes and genre scenes.

Roman artists did not merely copy Greek paintings. They reinterpreted them to Roman tastes, often emphasizing landscapes. Artists reduced the size of figures and focused instead on depicting craggy rocks and turbulent seas, delicate foliage, and airy skies. Roman artists also added new subject matter, especially during the second style, when they painted lifelike gardens behind their real-looking architectural scenes.

Roman artists also made technical innovations. They introduced the concept of achieving depth by diminishing the size of figures meant to be farther away. They developed *atmospheric perspective,* the technique of showing distant objects as hazier and more blue in color than objects nearby. After the decline of the Pompeiian styles and until about A.D. 400, portraiture was the predominate subject of Roman painting.

Asian painting

Asian paintings have been created by many cultures that differ from each other in time, geography, and social values. There are three main artistic traditions in Asian painting. One developed in southern Asia, especially India, but also in Indonesia, Sri Lanka, Nepal, and Tibet. Another tradition emerged in northeast Asia, primarily China, Korea, and Japan. The third comes from the Islamic countries that range from Spain to central Asia and northern Africa.

Indian painting is primarily religious art that deals with themes and beliefs related to the main religions of India—Buddhism, Hinduism, Jainism, and Islam. The earliest paintings in India developed in response to Buddhist needs to communicate religious ideas to the faithful. Paintings of deities and of stories associated with Buddhism covered the walls of temples and monasteries, as well as palaces and mansions.

The great Buddhist cave paintings at Ajanta in western India are the best existing examples of the early wallpaintings. Most of them were painted in the A.D. 400's, during the Gupta dynasty, an era known for great poetry, drama, and dance as well as the visual arts. The paintings provide information on court life as well as religious imagery.

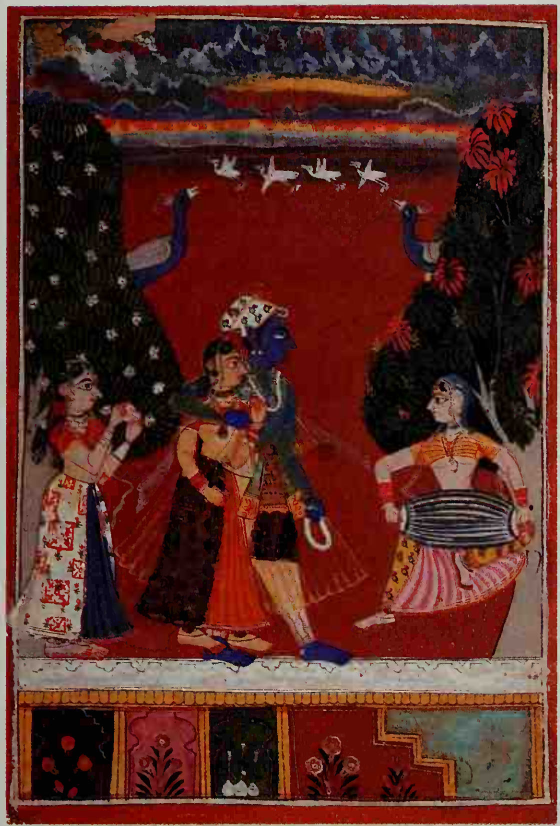
Most Indian painting was later done on palm leaves and still later on paper. This painting dates from the late A.D. 1000's. For the next 700 years, Indian painting was essentially an art of book illustrations, meant to be held and examined at close range. Painters used natural vegetable and mineral pigments and even added parts of insects to their paintings, all according to formulas passed down from master to pupil.

From the time of the Ajanta wallpaintings, Indian painting evolved in a direction that favored flat planes of vivid color, angular movement, and wiry line. By the early 1500's, this style, with large flat areas of bold color and simple compositions, was associated with the Rajput courts of northwestern India. These courts followed the Hindu religion. The painters in the Rajput courts chose stories of gods and mythical heroes for their themes. The life of the god Krishna was popular in every period of Rajput art. Krishna was the ideal child, lover, hero, and religious teacher, as well as the model for masculine behavior.

The ancient Hindu epics the *Mahabharata* and the *Ramayana* were also popular subjects. Another common subject was a collection of Indian musical compositions called *ragas.* Painters transformed poetic descriptions of these musical melodies, each with its own mood, into visual images called *ragamalas* (page 45).

The Muslim Mogul (or Mughal) dynasty conquered India in 1526 and reigned until 1761. Painters working in this dynastic period introduced new subjects—illustrated histories, literary works, and portraits. The scene' *A Ruler on Horseback Leading an Army Across a Battlefield* (page 45), from an illustrated history, reflects a new concern for detail and setting. This concern led to more complex compositions, subtle and varied color, and individual characterizations of figures.

Artists found continuous employment at Mogul courts. Under the Moguls, both Indian and Persian artists created a distinct style of manuscript illustration. The style combined Indian intensity and feeling for nature with Persian technical refinement and European realism. Knowledge of European art came from prints and paintings introduced by merchants and by Jesuit missionaries sent to India to convert the people to Christianity.



Some Mogul painting turned away from manuscript illustration to the production of individual pictures, such as portraits and studies of animals and flowers. These pictures were mounted in decorated borders and bound in albums.

Chinese painting is closely linked with the older art of writing and evolved directly from it. The Chinese developed beautiful handwriting, called *calligraphy,* as an art form. Chinese artists used the same tools for calligraphy and painting—a flexible brush, a silk or paper support, and an ink stick. The Chinese were writing on silk as early as the 400's B.C. Silk was adopted by painters who liked its smooth surface as early as the 200's B.C. Paper, invented in China, came into wide use for writing and painting by the early A.D. 300's.

The quality of the ink is important in Chinese painting. Artists make ink by mixing oil or soot produced from burned pinewood with glue and then drying it into a stick. This ink produces a lustrous black that, when diluted with water, creates a full range of tones from deep black to pale gray. To make liquid ink, the artist rubs the stick on a stone that has an indentation to hold a small pool of water. Brushes have an absorbent core and a flexible tip that create both flowing strokes and bolder, rugged lines of varying widths.

During the Han dynasty (202 B.C. to A.D. 220), great masters of calligraphy appeared, and writers composed essays devoted to calligraphy as an art form. The craft of beautiful writing was given prestige beyond its usefulness for communicating information. The flexible brush used for calligraphy could transmit the hand movements of the writer, which led to the belief that one could interpret character and personal qualities through calligraphic forms.

Gu Kaizhi was one of the earliest and greatest of the ancient painters. He lived during the Six Dynasties (A.D.

220-589). He was famous for painting figures and portraits, but he also painted landscapes. The most famous work attributed to him, but probably a copy, is the hand scroll *Admonitions of the Instructress to the Court Ladies* (page 46). It consists of texts that alternate with illustrations of figures set in a plain background. The painting conveys the character of the early Chinese painting style in the vitality, delicacy, and firmness of the brushstrokes, as well as in the faces that display character and emotion.

Records tell of many great painters who lived during the Tang dynasty (618-907). Tang artists painted portraits, animals, and scenes of court life, but none of their works has survived. Literary sources report that the palaces and temples of the capitals were covered with magnificent wallpaintings. Such paintings in tombs near Xi'an suggest the high quality and dignified character of this Tang art. Cave paintings from western China convey the Buddhist imagery of the period.

The most important development in Chinese painting was the appearance of landscape as an independent subject and not merely as a background for figures and human action. A philosophy called *Neo-Confucianism* was responsible for making nature a proper subject for art. The philosophy flourished during the Five Dynasties and Ten Kingdoms (907-960) and the following Song dynasty. Neo-Confucianism taught that nature is infinite and eternal and can be studied and understood.

The Song (or Sung) dynasty became one of the classic periods of Chinese painting. Historians have divided the dynasty into the Northern Song (960-1127) and Southern Song (1127-1279). Beginning with the Song dynasty, great masters frequently distinguished themselves in both painting and calligraphy. The high esteem given to calligraphy carried over into calligraphic painting.

The earliest surviving Chinese paintings are funeral banners on silk from the 100's B.C. However, the most important Chinese painting formats are the horizontal hand scroll, which is read from right to left; the vertical hanging scroll; and small paintings that served as leaves for albums.

During the Northern Song era, landscape came to dominate painting. Painters used calligraphic brush technique to represent rugged mountains and flowing streams, and also to reflect Chinese attitudes toward the natural world. They worked solely in tones of black ink and used brushstrokes to create mass and texture.

Artists painted large compositions on horizontal hand scrolls and vertical hanging scrolls, such as Fan Kuan's *Travelers Among Mountains and Streams* (page 34). This work is typical of the monumental landscapes of the time that portray an ideal, permanent, and ordered vision of the world. It is carefully organized and filled with complex detail.

Beginning with the Song period, the Chinese distinguished between amateur and professional ideals in painting. Amateurs were scholars or government officials who turned to painting as a means of self-

expression. These painters were not concerned with realism and artistic technique, but with the expression of individual character. Chinese art criticism from the mid-1300's to the early 1900's supported the scholar-painter ideal as the only acceptable one.

The ideal of the scholar-painter became dominant during the Yuan period (1279-1368), a major era in Chinese painting. The art of the Yuan period reached its peak with the work of the "Four Masters"—Huang Kung-wang, Ni Tsan, Wu Chen, and Wang Meng.

Through the influence of the Yuan painters, painting came to function less as an image of nature than as an expression of style. For the amateur painters, the subject, whether it was landscape, bamboo, or an orchid, was a means through which they could reveal their personality. Inscriptions came to play a large role in their paintings. The artists wrote poems on the paintings as a further expression of their feelings. These calligraphic inscriptions formed part of the overall design.

Song painting, especially that of the Southern Song Academy, an art school in Hangzhou, represented the conservative current in Chinese painting. Unlike the extremely personal work of the painters of the Yuan period, Ma Yuan and other masters of the Southern Song Academy expressed a yearning for the simple and the restrained.

Several major painters were associated with the Chan sect of Buddhism, known as Zen in Japan. These painters worked in monasteries near Hangzhou. They painted subtle, refined pictures of great spiritual intensity. The rapid brushwork of the great Chan painter Liang Kai appears in his hanging scroll *Hui Neng, the Sixth Patriarch, Chopping Bamboo at the Moment of Enlightenment* (this page).

The Song artists divided the picture surface into dense and empty areas. They defined rocks and tree trunks by contour lines and texture. They sometimes added light, translucent color. They painted decorative bird and flower pictures in ink and opaque colors. This style was carried to Japan in the 1400's by Buddhist monk-painters such as Sesshu and became the foundation of Japanese ink painting.

The Manchus invaded China in the mid-1600's, taking power and establishing the Qing dynasty (1644-1912). The Manchus looked back to the Yuan period for artistic inspiration. They gave official support and recognition to the *traditionalists,* those painters who carried on the tradition of the Yuan painters. However, the greatest painters of the Qing dynasty were called *individualists* because they could not be classified. The finest Qing painter, Dao-Ji, declared that he had no style and that he studied past masters only to transform them. For examples of Chinese painting, see **China** (The arts); **Wang Wei**.

Japanese painting. Japan's long cultural interaction with China affected the entire history of Japanese art. Painting began to flourish with the coming of Buddhism from China and Korea in the mid-500's. During the late 500's and the 600's, Buddhist monks from the Asian mainland brought both painting and artists with highly developed styles and techniques.

The Chinese-inspired style was transformed to more Japanese tastes in Buddhist painting of the Heian period (794-1185), named for the capital of Heiankyo (now Kyoto). Exquisite color and gold leaf enhanced the painting surface, creating an impression of restrained elegance. This style reflected the tastes of the aristocratic culture of the Heian period.

With a rich tradition of forms and materials derived from China, Japanese artists began during the 900's to create works that expressed a truly national artistic experience. This distinctively Japanese-style painting was known as *Yamato-e.* The style used mainly nonreligious subjects, especially landscapes, and was also associated with the Heian court aristocracy. This national style is closely linked to classical Japanese literature and to its poetic response to the changing seasons and the beauty of nature.

Yamato-e hand scrolls also illustrated Japanese tales. These paintings reflect the elegance and refined taste of the Heian court. Painting of the time reached its peak in scrolls narrating *The Tale of Genji* (page 29), a novel by the court lady Murasaki Shikibu in the 1000's. The novel is perhaps the greatest work of Japanese fiction. Professional artists painted the scroll in court workshops. The artists sought to capture the emotion and mood of the novel rather than depict it literally. The paintings have a strong abstract design and a lyrical color sense. For other examples, see **Japan** (History); **World, History of the** (The rise of Japanese civilization).

Both religious and nonreligious narrative hand scrolls flourished in the late Heian period and the Kamakura period (1185-1333), named for its capital, Kamakura. These inventive visual narratives include action tales presented in uninterrupted pictorial sequences.

A new style of painting arrived from Song and Yuan China in the late Kamakura period in the form of *monochrome* (single color) ink paintings. This style was brought to Japan by Chinese monks coming to work in Japanese Buddhist monasteries. In addition to ink painting, the monks introduced Song *polychrome* (multicolored) realistic portraits into Japan.

Monochrome ink painting dominated Japanese painting well into the 1500's. Early Japanese monk-artists depicted the founders of their faith as well as animals and plants, such as the tiger and the orchid, which had symbolic meanings. The painters' colleagues and friends often inscribed poems in the Chinese style on the upper part of the paintings.

Ink paintings became a truly Japanese form with the work of two monk-painters of the 1400's—Tensho Shubun and his pupil Sesshu. After traveling to Korea in 1423, Shubun introduced a more sweeping landscape style. He painted on screens and scrolls, using ink washes and fine black lines. Sesshu traveled to China in 1467, where he came into contact with classical Ming painting. On his return in 1469, he worked in a variety of styles and techniques, a diversity shared by many later

Japanese painters. Sesshu created technically superb and powerful compositions in both ink and color. After Sesshu, ink painting emerged as a nonreligious style no longer associated with the Buddhist community.

The Kano school, founded by Kano Masanobu in the late 1400's, became one of the most powerful artistic groups in Japanese art for centuries. Kano Motonobu, his son, was the school's principal teacher. Kano school artists painted traditional Chinese themes in a style of balanced composition and sharply defined line. Beginning in the 1500's, Kano paintings included Japanese subjects depicted in color. Motonobu's grandson Kano Eitoku created a new style in which he reduced forms to bold and simplified shapes that could be understood at a glance. In paintings such as *Cypress* (this page), Eitoku created a new style. He departed from the previous Kano emphasis on delicate, single-colored paintings. Instead, he painted large works in a flat, bold-patterned style using gold leaf and color. He painted *Cypress* on the large surface of an eight-panel folding screen. His new monumental style glorified the power of his patrons, who were military warlords.

An artistically rich period emerged during the Edo era (1603-1867), named for Edo (now Tokyo), the political center of Japan. This period is also called the *Tokugawa,* after the name of the ruling dynasty of *shoguns* (generals). Artists drew on various traditions—Japanese, Chinese, and Western. This interaction of traditions gave artists access to a large artistic vocabulary. The Kano school continued to prosper as the official painters of the Tokugawa shoguns. The basic style of Edo painting came from the Kano school together with that of the Tosa school, which took its subjects and techniques from classical Yamato-e. The later Edo period also produced realistic landscapes painted in color.

The building projects of the shoguns were important training grounds for painters and craftworkers and provided many opportunities for professional artists. Artists painted screens and other works that decorated the new buildings. The growth of castle towns enhanced patronage for regional painting styles. The aristocracy living in Kyoto was the official patron of Tosa school painting, but wealthy merchants also supported it.

In the early 1700's, the growing middle class provided new patrons whose tastes ran from elegant and refined paintings to simple folkish art. This period is more familiar to the Western world through the multicolored woodblock prints called *ukiyo-e* (pictures of the floating world). Ukiyo-e depicted the theater and other urban amusements. The Japanese referred to these passing scenes of city life as the "floating world."

Islamic painting is art associated with the religion of Islam, first preached by Muhammad in the A.D. 600's in what is now Saudi Arabia. Calligraphy is the supreme art in the Islamic civilization because the Islamic holy book called the Koran was written in the beautiful script of the Arabic language. Muslims believed that calligraphy carries the divine message of the Quran in the form of the writing as well as in the meaning of the words.

Islamic art reflects a complex attitude toward the representation of living forms. Islam prohibits the depiction of animal and human forms in all art related to the religion. As a result, religious art often combined calligraphy with floral or geometric designs. However, Muslim princes inherited a liking for paintings of human beings and animals from the cultures that Islam had conquered. Throughout the history of Islam, privately owned nonreligious paintings include lifelike images.

The best-known Islamic paintings are book illustrations. Many of these paintings illustrate classics of the literature of Persia (now Iran), beginning in the 1200's. One popular subject for painters was the *Shah-Namah (Book of Kings).* This long work was written by the poet Firdausi and completed about 1010. The *Shah-Namah* ranks as the national epic of Persia, consisting of episodes from Persian history mingled with myths and legends. An illustration from the epic called *Bahram Gur Hunting the Wild Ass* (this page) was painted by an artist in the city of Tabriz. His painting shows the exquisite drawing and jewellike color that characterizes much of Islamic painting.

Medieval painting

Historical background. The Middle Ages began in the A.D. 300's, during the last years of the Roman Empire, and ended with the emergence of modern nations in the 1400's. The Middle Ages overlapped with the early years of the Renaissance in Italy.

During the Middle Ages, Europe was divided into small territories controlled by a military aristocracy. The economy was based on agriculture, and most people lived in self-sufficient villages. Gradually, territories were organized into larger units under a system called *feudalism.* Under feudalism, landowning nobles gave other nobles the use of land in exchange for their allegiance. Eventually, powerful families established kingdoms and ruling dynasties. Trade increased, craftworkers organized into guilds, and villages grew into towns.

The Christian church replaced the Roman Empire as the dominant organization in Europe. The most powerful political and religious leader in the West was the pope. The Byzantine Empire controlled much of the East, and Eastern Christians belonged to one of the Eastern Orthodox Churches. Muslims eventually controlled the Near East, north Africa, and southern Spain.

Former Roman provinces became dioceses of the church. Monasteries and convents served not only as religious institutions but also as hospitals, schools, and cultural centers. For centuries, monks and nuns created the finest medieval art and architecture.

Most people during the Middle Ages lived in relatively isolated communities. The Christian church, however, remained an international organization ruled by the pope from his headquarters in Rome. The church encouraged people to travel, either on religious pilgrimages to the shrines of saints or by joining a Crusade. The Crusades were a series of military expeditions from 1096 to 1270 to take Jerusalem and Christian holy places in Palestine from the Muslims. Crusaders and pilgrims brought new ideas and art back with them. Medieval art reflects the contrast between regionalism, which consisted of local styles and techniques, and internationalism, which reflected a wider knowledge and view of the world.

Artists worked for the church or for royal and noble families. Most of the art made for aristocrats has been destroyed. Because art was preserved in the churches, most medieval painting that survives is religious art.

Church leaders were conservative in their taste in painting. Artists were required to make good reworkings of earlier art, not create something new. Originality and individuality in art were not considered important, and few artists even signed their work. Thus, artistic change came slowly.

Medieval paintings were either small or very large. The small paintings included *illuminated* (decorated) manuscripts along with images of Christ and the saints known as *icons.* Most large paintings were murals. Painters also designed tapestries and mosaics that decorated walls.

Early Christian and Byzantine art. In the 300's, Christianity became the official religion of the Roman Empire. Eventually, Christianity divided into two main branches, the Western church in Western Europe and the Eastern Orthodox Churches in the East.

The earliest Christian art in the West can be seen in the catacombs, which were burial chambers in Rome. The early Christians painted symbols of their faith, images of Christ, and stories from the Bible on the catacomb walls. After Christianity became the official religion of the empire, Christian artists continued to decorate the walls of funeral chapels with paintings as well as mosaics. For an example of catacomb painting, see **Bible** (picture: Scenes from Biblical stories).

The art made for the Eastern Orthodox Churches is called *Byzantine art* after Byzantium, the original Greek name of Constantinople (now Istanbul, Turkey), the capital of the Roman and then of the Byzantine empires. Byzantine artists painted murals and richly colored illuminated manuscripts as well as icons.

Worshipers were taught to *venerate* (show deep respect for) icons and looked at them when they prayed. The icon *Virgin and Child Enthroned with Angels and Saints* (this page) shows Mary holding the infant Jesus on her lap. The warriors Saint Theodore and Saint George stand guard as two angels look toward heaven. The Christ child and the angels are portrayed in an almost realistic style. The saints and the Virgin are flat and stylized. The warriors stare ahead with wide open eyes. Their bodies disappear under their patterned silk cloaks. Mary becomes a throne for her child rather than a living mother. For more information on Byzantine painting, see **Byzantine art**. For additional examples of Byzantine painting, see **Icon** and **Russia** (The arts).

Early medieval painting in the West. From the 300's to the 1000's, Western European art flourished in important and wealthy monasteries. Missionaries carried illuminated Gospels and other Christian art to new territories, spreading painting styles from place to place.

In the British Isles, Celtic and Anglo-Saxon monks made some of the most beautiful books ever created, notably the *Book of Kells.* This work is a *Gospel book*—that is, a book containing the four Gospels. Celtic artists decorated pages of the *Book of Kells* with complex combinations of letters, spirals, animals, and sometimes highly stylized human figures. The drawings are filled with bright, clear colors that make the page resemble a piece of enameled goldwork or an intricately woven carpet. For an illumination from this book, see **Manuscript**.

cational and cultural program as well as political and economic reforms. He understood the importance of education and set up schools and *scriptoria* (writing rooms in monasteries) throughout his empire. The art created in Charlemagne's empire is called *Carolingian.* The richness and variety of Carolingian art are reflected in the illuminated books made especially for the churches and monasteries that Charlemagne established.

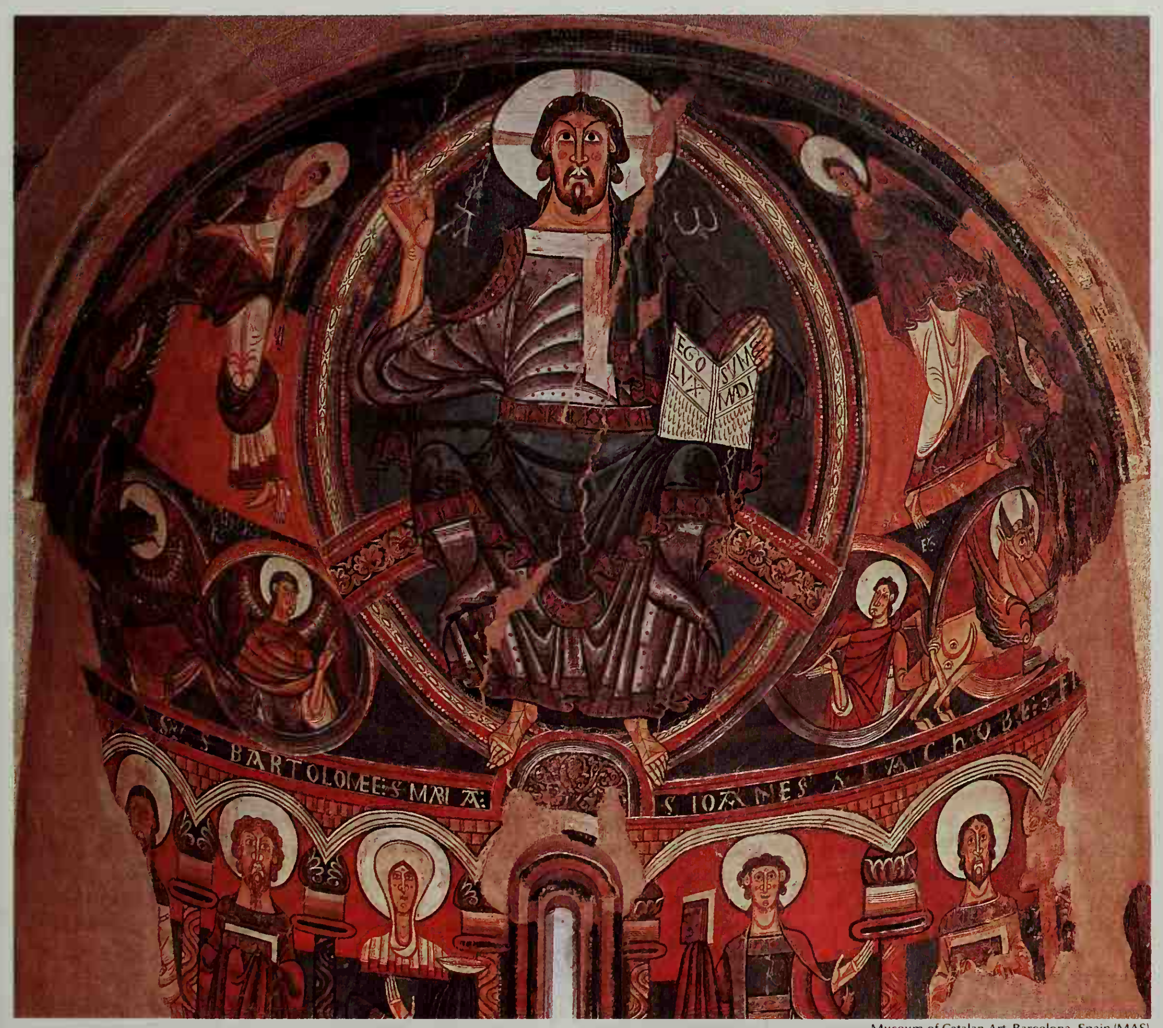
An example of Carolingian illumination is the Gospel book made for Archbishop Ebbo in a monastery near Reims, France (page 49). The illumination shows Saint Matthew, one of the Gospel writers, seated on a large red cushion with his feet on a footstool. He leans on his desk as he writes with a quill pen and holds a horn filled with ink. He is inspired by an angel, who appears in the upper right corner. The landscape, Matthew's togalike robe, and his furniture are copied from early Christian art. The artist used a fine brush to create a picture that looks almost like a pen drawing. The lines have so much energy and movement that they suggest the saint is caught up by intense religious feeling and the importance of his work. His hair is wild, and his clothes and body are twisted. Such linear energy resembles the complicated geometry of Celtic painting.

Romanesque painting flourished in Western Europe beginning about 1050. This art is not Romanlike, as the name suggests. The name was given to the style in the 1800's by historians who related the architecture of that period to the round arches found in Roman buildings.

During Romanesque times, wealthy monasteries became the most important patrons of the arts. Many churches were built, and old buildings were enlarged and redecorated. Mural paintings became important.

The wall behind the altar at the Church of San Clemente of Tahull in Spain was painted with a huge figure of *Christ of the Apocalypse* (page 51). He sits on a rainbow with His feet on the world, holding an open book inscribed "I am the light of the world." He raises His right hand in blessing. Around Christ, fitting the curve of the wall, are the four authors of the Gospels. They hold their books and the animals that symbolize them. Paintings of the Virgin Mary and the apostles appear on the wall below Christ.

The San Clemente artists did not try to make the figures look like living people. Instead, they followed the traditional way of representing the images. The different sizes of the figures established an order in which Christ, the most important figure, is the largest. All the figures are flat and stylized. They have heavy dark outlines, simple geometric shapes, and bright colors that would be easy to see even in a dark church lit by candles. For another example of Romanesque painting, see **Bible** (picture: Saint Jerome).



Gothic painting. The Gothic period lasted from about 1150 to about 1400. Kings gained control over feudal lords and established nations. Cities with merchants and craft guilds became more important than agricultural villages. Universities replaced monasteries as centers of learning and culture. Professional painters and scribes, not monks and nuns, painted illuminations.

Gothic painters looked at all of the world, not just human beings. At first, they studied the details of nature, including leaves, flowers, animals, and insects. Gradually, they painted human beings acting out stories that suggest the natural world.

In the illumination *Abraham and the Three Angels* (this page), the Biblical patriarch Abraham meets three young men, who are angels, under an oak tree. He invites them home and gives them food. The painting shows Abraham and the angels twice. First, they meet on the left side of the painting. Then, on the right, Abraham kneels in front of the table as his wife, Sarah, stands in the doorway of their home. To Christians, the three angels symbolized the Trinity as well as the Biblical story of Abraham and Sarah's generosity.

The figures in the illumination look more like real people than Romanesque figures, but they are still stylized. The figures are tall and slender and stand in elegant poses. Their faces are idealized. Although they gesture vigorously, their graceful bodies seem to disappear under the elegant drapery patterns. Their long fingers seem too delicate to grasp anything, and the figures appear to take up no space against the gold background. Even the table with the dishes and food becomes a flat pattern. Yet the artist has begun to look at the world around him. The oak tree has an important position in the center of the painting, and its leaves and acorns are carefully shown. The architecture that frames the scenes is copied from a real building, La Sainte Chapelle in Paris.

Some Gothic artists painted on a large scale, making

pictures called *cartoons* for weavers to copy for tapestries that covered church and castle walls. Artists also painted huge stained glass windows.

Especially beautiful illuminated books were created in the late 1300's and early 1400's for the Duc de Berry, a brother of the French king, Charles V. The duke collected manuscripts and employed a number of painters, the most famous being the three Limbourg brothers, Pol, Herman, and Jean. The Renaissance

The Renaissance was a great cultural movement that began in Italy in the early 1300's and spread to other European countries. The word *Renaissance* comes from a Latin word meaning *rebirth.* What was actually reborn during the Renaissance was an interest in *classical antiquity,* the culture of ancient Greece and Rome.

The 1300's. By the 1300's, such Italian writers as Giovanni Boccaccio, Dante Alighieri, and Petrarch were studying Roman literature and the world around them. They began a movement called *humanism,* which stresses the importance of human beings (see **Humanism**). Humanism had a profound influence on painting. Painters began to look with new interest at the art of ancient Greece and Rome and at their fellow human beings.

The change from medieval to Renaissance painting can be traced in the styles of Giovanni Cimabue and his pupil Giotto. A detail of Cimabue's *Madonna Enthroned with Angels* appears in the **Renaissance** article. A comparison of that painting with Giotto's *Madonna Enthroned with Saints* shows the difference between Cimabue's late medieval style and Giotto's style, which was a forerunner of Renaissance painting.

Cimabue's painting achieves an otherworldly appear-

ance. The artist placed an abstract network of gold lines on the Madonna. The lines seem to make the figure flatter and almost transparent, as if the gold were shining through her. Giotto's composition occupies a more natural physical space. He used white highlights on Mary's lap and chest to suggest physical bulk and presence. Giotto's concern with solid forms and real space demonstrates an interest in the natural world that was strikingly different from the formulas of medieval painting.

Giotto was one of the most remarkable painters in art history. Giotto's subjects were Biblical stories and the lives of saints, but he was interested in how people looked and acted. His work indicated a change from symbolic art of the Middle Ages, which concentrated on religious ideas, to the more humanistic art of the Renaissance.

As Giotto studied people, he copied their gestures and expressions in paintings like *Joachim with the Shepherds* (this page). The scene is also known as *Joachim Takes Refuge in the Wilderness.* Joachim is downcast because he and his wife, Saint Anne, have no children. The shepherds seem worried and curious. A dog jumps up to greet a stranger, an angel who will announce to Joachim that his wife will become the mother of the Virgin Mary. Giotto painted the shepherds' hut and the rocks and trees of the landscape in three-dimensional forms, not the flat medieval style. He even painted blue sky instead of the gold background that Gothic painters used. Giotto emphasized the human characteristics of his figures, portraying the weight of their bodies under heavy drapery by modeling in light and shade. For more examples of Giotto's painting, see **Christianity; Jesus Christ** (picture: Jesus's childhood).

As artists became more highly trained in painting techniques and the ideas of humanism, they altered their styles. There was a greater demand for realistic images. Artists made discoveries that led to new ways of portraying the human form, pictorial space, color, gestures, and the placement of figures. For example, Renaissance painters rediscovered the rules of *linear perspective,* a mathematical system for showing depth on a flat surface. The technique had been largely abandoned during the Middle Ages.

The center of early Renaissance painting was the city of Florence. In 1348, a terrible outbreak of plague called the *Black Death* killed many Florentines. Only a few artists in the city survived. The destruction caused by the plague reduced interest in the arts and inhibited developments in painting initiated by Giotto. As a result, further developments in Renaissance painting did not occur until the 1400's.

The 1400's in Renaissance art history are sometimes called the *Quattrocento,* an Italian word that means *four hundred.* This century was a period of intense political,

economic, military, religious, and artistic activity.

An early masterpiece of the Quattrocento is Masaccio's *The Tribute Money* (page 52), a fresco painted in a church in Florence. In the painting, Masaccio demonstrated many of the stylistic innovations that characterized Renaissance painting. These innovations included linear perspective, anatomical accuracy, and evenly spaced figures.

Masaccio's fresco tells a story from the Bible. Jesus and His disciples have gathered near a town controlled by the Romans. A Roman official demands that the group pay the tax necessary to enter the town. Although the disciples protest, Jesus orders Peter to look in the mouth of a fish, on the left, where the disciple finds the money to pay the tax collector, on the right. The perspective establishes a horizon line at about the level of the heads of the grouped figures, with Jesus in the middle. The poses of the bodies follow the laws governing human anatomy, and the gestures are simple and clear.

Fra Angelico worked about the same time as Masaccio, but in a simpler style, as in his fresco *The Annunciation* (this page), painted in a convent in Florence. Fra Angelico understood perspective and used it in his painting, but he did not follow Masaccio's interest in anatomical accuracy and forceful gestures. The Madonna sits modestly as she hears the Angel Gabriel announce that she will become the mother of Jesus. Gabriel kneels in a position that shows great respect. The angel appears quiet and devoted, and his clothing falls in neat, simple folds.

In northern Italy, Andrea Mantegna produced masterworks of Renaissance art. Mantegna learned much from the Renaissance sculptor Donatello, who revived classical ideas of physical beauty by sculpting the first large nude figures since ancient times. Mantegna also studied the ancient ruins of Italy. In *Saint Sebastian* (page 54), Mantegna revealed his interest in anatomy, the ideal figure, and antiquity. Sebastian was an early Christian saint. After the Romans discovered he was a member of the outlawed Christian faith, they shot him with arrows. Mantegna may have chosen Sebastian as a subject because it gave him the opportunity to portray an ideal human figure bound to a classical ruined arch. The painting's realistic anatomical detail and the heroic character of Saint Sebastian make it typical of the interest in nature and humanism popular in Italy.

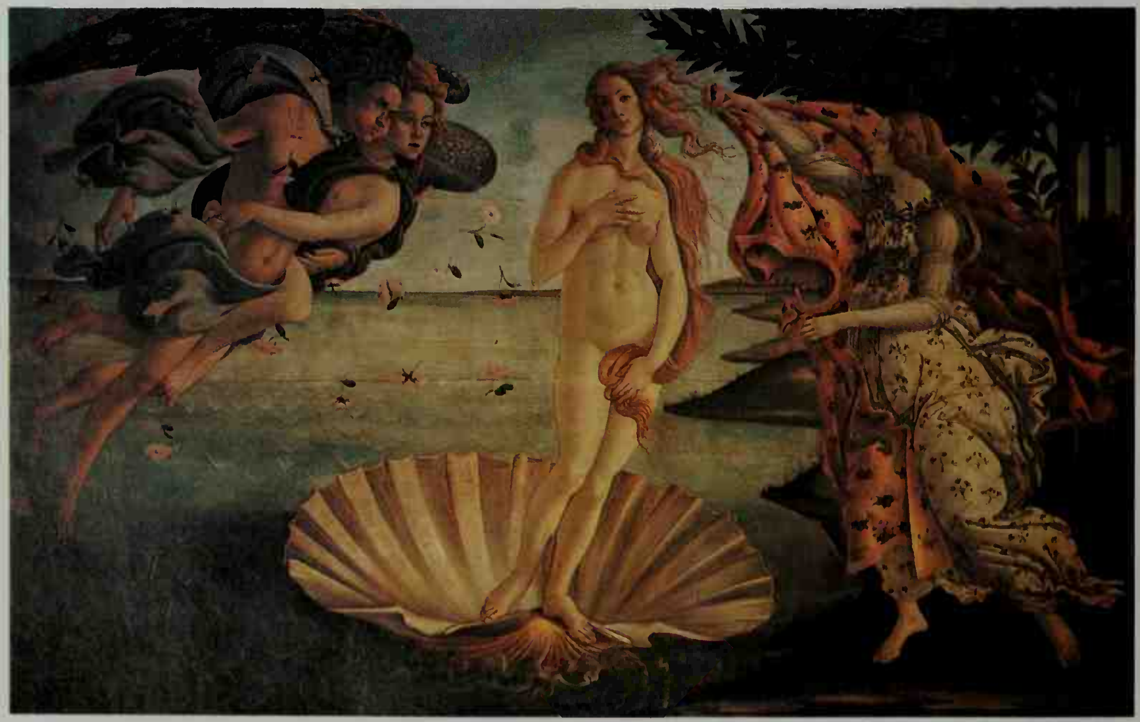
Sandro Botticelli absorbed the technical accomplishments of earlier Renaissance artists and added a personal poetic style. Botticelli cared less about realism than he did about decorative effects. His *Birth of Venus* (page 54) shows Venus, the Roman goddess of love and beauty. She has just arrived on shore, blown there by gods of the wind called Zephyrs, on the left. Venus is attended by another mythological deity called an Hour, on the right, who is about to cloak Venus's naked beauty. The painting has a fine delicacy created by the emphasis on V-shaped waves and flowing clothing and hair. The figure of Venus stands in a curved, almost unnatural pose. The result is a painting less realistic than was common for the period.

In contrast to Botticelli, Leonardo da Vinci almost never experimented with decorative or ornamental effects. Instead, he concentrated on what he thought was a scientific and rational approach to art. At the same time, he was interested in conveying feelings with his art.

Leonardo's *Madonna of the Rocks* (page 55) represents Jesus and John the Baptist as infants, the Virgin Mary, and an angel in a dark landscape. Leonardo's understanding of the human body and his interest in new lighting effects appear in the painting. Unlike Masaccio and Mantegna, Leonardo did not put his figures in a clear atmosphere so the viewer could see all the details of the human forms. Instead, he blurred and darkened his outlines with shades of color in a technique called *sfumato* (smoky). The sfumato submerges the figures and landscape in shadows that help create a peaceful mood. The dusky light reveals the protectiveness of

Mary, the sweetness of the children, and the gentle gracefulness of the pointing angel. The arrangement of the figures in a pyramid is typical of many Renaissance paintings and adds to the painting's sense of stability and calm.

The High Renaissance is the term given to the years from about 1500 to 1525 in Italian painting. This period reached its peak through the powerful patronage of Pope Julius II and the work of such artists as Michelangelo and Raphael.



Painters of the High Renaissance continued and even emphasized elements of earlier Renaissance art. These elements included the realistic treatment of space, an understanding of the human body, the clear use of colors, and formal compositions. But differences did emerge. Figures in High Renaissance paintings have a strong presence not often seen earlier. Figures portrayed as stiff and immobile in the works of the 1400's were shown twisting and spiraling in space. Artists stressed anatomy. Gestures became broader, and facial expressions stronger and more commanding. Compositions that had been shallow grew deeper, and painters tried to make the space more convincing.

Michelangelo. Among the early masterpieces of the High Renaissance were Michelangelo's frescoes for the Sistine Chapel commissioned by Pope Julius II. The chapel is next to St. Peter's Basilica in Rome. The pope considers the Sistine Chapel his own private chapel. In addition, the Sacred College of Cardinals meets there to elect new popes. Michelangelo worked over a period of about four years on the ceiling frescoes. He chose

scenes from the Book of Genesis that illustrate events from the Creation to Noah and the Flood.

Michelangelo's fresco *The Creation of Adam* (page 56) from the chapel ceiling is characteristic of Renaissance humanist attitudes. In the painting, God, portrayed as an elderly man, hurtles with great force and speed toward the passive, awakening Adam. Adam is already alive, even before God touches his finger. The creation about to occur may be the birth of human potential, the enabling of Adam to choose whether to ascend to greatness or decline into sin.

Michelangelo's figures are strongly three-dimensional, well muscled, and anatomically accurate. Adam is already physically perfect, an ideal male nude. Michelangelo's powerful rendering of the human form enhances a quality called *terribilità* (awesomeness), for which the artist became noted. The "awesomeness" refers to the barely contained energy of the figures. For other examples of Michelangelo's painting, see **Michelangelo.** See also **David; Isaiah, Book of; Jeremiah, Book of; New Testament; Religion** (A doctrine of salvation); **Sistine Chapel.**

Raphael. While Michelangelo was working on the Sistine Chapel, Raphael was painting the *School of Athens* in a nearby room in the Vatican. The painting appears in the **Raphael** article. Many historians see the *School of Athens* painting as the fundamental expression of the High Renaissance. It shows the ancient Greek philosophers Plato and Aristotle acting out their individual philosophies. Plato, pointing upward, represents the tradition of philosophy concerned more with ideas than with particulars, which finds its truth descending from above. Aristotle gestures outward to indicate his reliance upon evidence that can be found in the real world. Arranged near Aristotle are the scientists and mathematicians of earlier ages. To Plato's right are philosophers, who draw conclusions from logical assumptions and pure reason rather than actual experience.

Raphael arranged the figures in the *School of Athens* in a deep circle. The lighting is clear and even. The space is generous and rational. The figures are evenly spaced. Everything is calm, centered, logical, and visually understandable.

Raphael achieved a more intimate grace with his *Madonna of the Goldfinch* (this page). Mary sits calmly with the Christ child and His cousin John the Baptist. Raphael placed this tranquil family in a peaceful landscape of clearly outlined forms that represents the Renaissance ideal of harmony and balance. For other examples of Raphael's painting, see **Europe** (The arts); **Plato; Raphael; Renaissance** (The Italian Renaissance).

Venice stressed a poetic mood and the mystery of nature. Giorgione's *The Tempest* (this page) depicts a dramatic landscape. In *The Tempest,* the colors of the vegetation are rich and deeply green. A storm dominates the center of the composition. Historians do not agree on the meaning of this painting. It may simply be an expressive scene of a young woman nursing a child while a man stands nearby.

Sebastiano del Piombo was a Venetian painter whose early works were strongly influenced by Giorgione's style. However, Sebastiano gained his greatest fame after moving to Rome in 1511. The finest paintings of his Roman years are portraits, notably *Portrait of Pope Clement VII* (page 57). Sebastiano painted the pope as a man of grave and compassionate appearance and character. The pope, a member of the powerful Medici family in Florence, was a patron of such artists as Michelangelo and Raphael.

Venetian artists loved color. Titian's *Crowning with Thorns* (page 58) shows a traditional religious scene, Jesus being tormented by Roman soldiers as they push a crown of thorns on His head with long poles. Titian's painting is troubling and emotional. The scene portrays great suffering and passion. Titian evoked emotion by setting the figures in a darkly lit passage. He painted the figures loosely, brushing on bold strokes of color, so the figures have an incomplete, nightmarish quality. By blurring the edges and using rich, dark colors, the artist created a vague and threatening feeling.

Paolo Veronese used the coloristic tradition of Venice to paint scenes of spectacular beauty. His enormous painting *Feast in the House of Levi* (page 59) was originally condemned by church officials who thought it was a painting of the Last Supper. The officials complained about the presence of "buffoons, drunkards, dwarfs, Germans, and similar vulgarities" at the final meal shared by Christ and His disciples. Veronese then changed the painting's title to reflect an episode in which Jesus brought His message to sinners. Whatever the actual subject of the work, it portrays an exuberant, festive joy of life. The setting is magnificent, the scale huge, and the background typical of Venice in the 1500's. All the figures, including the dog and cat, enhance the atmosphere of color and delight.

Mannerism is the name given to a new style that emerged about 1520 in central Italy. The term *mannerism* comes from an Italian word that means *style* or *manner.* Mannerist painters directly flouted Renaissance principles of rule, order, and design. Instead of har-

mony, the mannerists sought strain and discord. They created puzzling variations in scale and space, and emphasized unbalanced compositions and harsh colors.

By challenging artistic tradition, mannerism may have represented some crisis of the time, such as a loss of faith in traditional values. However, it seems more likely that the mannerists were interested primarily in experimenting with style and inventing something new in painting.

Mannerism came to Venice late in the 1500's in the art of Tintoretto. His bold and dramatic *Last Supper* (page 59) contrasts with most previous versions of this scene. In the upper room of a Jerusalem inn, Jesus meets for the last time with His disciples and tells them of His coming betrayal and death. Tintoretto placed the supper table on a diagonal, drawing the viewer backward into deep space. The light illuminates individual heads but creates no general clarity. Phantom angels sweep into the room and circle about the lantern suspended from the ceiling.

Like Veronese, Tintoretto included a number of details, such as the cat sticking its head into a basket of dishes. However, the overall effect is threatening. The exaggeration of space, the distortion of lighting effects, and the excitement of some of the gestures mark this painting as a late mannerist work. It also has many stylistic characteristics associated with the next age of European painting, the *baroque*.

The northern Renaissance. Italy was the home of the Renaissance, primarily because so much classical tradition of ancient Greece and Rome survived there. But northern Europe also produced a rich and fascinating art during the 1400's and 1500's. The center of this culture was an area in northern Europe called Flanders, which lies primarily in modern France and Belgium. Germany also produced great Renaissance painting.

People from Flanders were called Flemish. The Flemish painters cared less than the Italians about a mathematically accurate technique for perspective or a classical sense of the human form. Instead, they concentrated on building their paintings through precise details and a sense of the light falling across the picture.

The Flemish artist Jan van Eyck painted *The Annunciation* (page 28), a work with a vast variety of detail and symbolic meaning. Van Eyck was among the first European artists to work entirely in oil paint. The technique lent itself to painting highly detailed images. The precision of detail appears in the glass windows as well as in the floor patterns. Van Eyck represented every strand of the brocade on the Angel Gabriel's cloak. The light coming through the windows behind Mary has been observed so carefully that the individual panes of the window all differ from one another.

For van Eyck, the entire range of details and colors in the visible world was significant. An Italian artist would suppress "unnecessary" details, but van Eyck attempted to capture all the particulars of a scene. These details express meanings. For example, the single top window suggests the single God of the Old Testament. The three windows below symbolize the Holy Trinity of the New Testament. For other examples of van Eyck's paintings, see **Jerome, Saint**; **Renaissance** (picture: A northern Renaissance painting); **Van Eyck, Jan.**

painters in the 1400's was Rogier van der Weyden. While van Eyck was objective, van der Weyden was deeply subjective. His *The Descent from the Cross* (page 60) pushes the figures close to the viewer. The figures, nearly life-sized, produce an eerie effect because they look like painted statues in a wooden box. Emotions range from grim despair to heartbreaking anguish. Tears roll down Mary's face as she faints in sympathy with her Son's suffering.

Both van Eyck and van der Weyden remained largely free of the influence of Italian art. However, by the 1500's, the Italian Renaissance style had spread throughout Europe. One Flemish artist of the 1500's stood apart from the prevailing Renaissance styles and worked in an individual manner. Pieter Bruegel the Elder produced no school or following, other than the art of his own children. His reputation ranks high today, but for many years after his death in 1569, he was often considered as simply a painter who poked fun at the peasants of his day. However, modern historians generally see a more serious, almost philosophical side to Bruegel's art.

In his *Landscape with the Fall of Icarus* (page 60), Bruegel portrayed the Greek myth of young Icarus. The boy's father, Daedalus, fashioned wings for his young son from bird feathers and wax. Daedalus warned Icarus not to fly too close to the heat of the sun. The boy ignored the warning and flew so near the sun that the wax in the wings melted. Thus, as a consequence of his pride and foolhardiness, Icarus plunged to his death in the sea.

Bruegel's figures are relatively simple and round. He painted his landscape viewed from above, and his perspective is difficult to analyze. Bruegel saw the story as if

it were occurring off the coast of Flanders, while a typical Flemish peasant plows his land. Nearby a ship sails. Two legs sticking out of the green water at the lower right provide the only evidence of Icarus's death. The drowning seems almost insignificant in the larger scheme of things. In the humanistic tradition of Italian art, the central event in a story almost always was placed at the center. But in Bruegel's painting, greater forces seem at work. Human beings, despite their pride, play only a small part in the world. For other examples of Bruegel's painting, see **Bruegel, Pieter, the Elder; Folklore; Tower of Babel.**

Albrecht Dürer was the greatest German painter of the Renaissance. He made two trips to Italy, one in 1494 and the other in 1505, hoping to discover the secret of Italian art. He never found what he believed to be the hidden formula for creating beautiful art. But he absorbed the Italian idea of the artist as important to society.

In the art of the 1500's, the portrait was a document that recorded the social position, class, occupation, or other significant aspect of the sitter. In Dürer's *Self-Portrait* (page 61), the artist made himself look like Jesus Christ. Dürer showed himself formally from the front. The portrait depicts a Christlike image, with wide staring eyes and long hair and beard. In this self-portrait, Dürer compared artistic ability with the creative power of Christ. The painting reflects the Renaissance idea of the artist as a genius. See also **Dürer, Albrecht.**

The 1600's and 1700's

Baroque is a term that originally described art that developed in Italy about 1600. The movement lasted until about 1750 in areas of Germany and Austria. The term was first used in an unfavorable way to describe the showy, extravagant art that followed the High Renaissance. However, the term lost its negative meaning and now refers loosely to all European art and architecture of the 1600's.

Applied to painting, *baroque* refers to the works of a varied group of artists in Western Europe. The works of these artists reveal distinctive national styles. These styles were supported by the Roman Catholic Church in Italy and Flanders, monarchies in France and Spain, and the powerful middle class in the Netherlands.

Despite the distinctive stylistic characteristics associated with each country, some unifying features exist in baroque painting. In general, baroque artists painted large-scale works of dynamic subjects that are realistic and emotionally intense. Artists expressed these qualities through active figures arranged diagonally within the composition. Strong colors and sharp contrasts of light and shadow heighten the theatrical presentation of the subject matter.

Baroque painting began in Roman Catholic countries where the church was confronting the effects of the Reformation. The Reformation was a religious movement that led to the establishment of Protestant churches. The Reformation prompted the Catholic Church to seek new ways to reach the faithful through art. In Catholic Italy and Flanders, artists produced works that taught religious doctrine in an easily understood fashion. Magnificent altarpieces proclaimed church beliefs clearly and directly. These two qualities are evident in the paintings of the foremost Italian baroque artist, Michelangelo Merisi da Caravaggio.

Caravaggio. Baroque characteristics that visually promote and defend the Roman Catholic faith appear in Caravaggio's *Conversion of Saint Paul* (page 62). The painting portrays the moment when Saul falls from his horse, converts to Christianity, and adopts his new name, Paul. The startling event occurs in the foreground of the pictorial space. Caravaggio intensified the drama by using abrupt contrasts of light and shadow, called *tenebrism.* The unidealized presentation of Paul, his attendant, and the horse spoke directly to the faithful. They would respond instinctively to the natural, convincing conversion of a sinner into a saint. Some artists and patrons of the time considered the realistic portrayal of such religious themes too natural. Church patrons rejected Caravaggio's altarpieces as vulgar and unsuited to a religious environment.

Caravaggio worked *alla prima*—that is, he painted directly onto the primed canvas in one layer, without preparatory painting underneath. His spontaneous method of creating his compositions differs from the deliberate approach of High Renaissance artists.

Artemisia Gentileschi was an Italian painter who became one of the most influential followers of the style

of Caravaggio. She employed realism and contrasts of light and shadow called *chiaroscuro* to portray powerful, determined heroines, especially from the Bible.

The Carracci family revived the Renaissance tradition of painting based on life drawings, sketches of nature, and models from antiquity. The three Carracci were Lodovico, the eldest, and his cousins, the brothers Agostino and Annibale. In 1585, they established an academy of art in Bologna, Italy. The conservative teachings of the school's leader, Annibale, continued the traditional style of the Italian Renaissance and offered an alternative to the radical art of Caravaggio. Annibale painted murals illustrating the classical approach to art by presenting a theme in a rational, controlled composition.

artist Peter Paul Rubens. Although he lived in Flanders, Rubens obtained many commissions from both public and private patrons throughout Europe. His popular paintings incorporate a balance of traditional classical idealism with the dramatic realism of his time.

In Rubens's *Battle of the Amazons* (page 29), the idealized nude figures are classical in origin, while the composition exhibits the active elements of Caravaggio's style. Like Caravaggio, Rubens conveyed the drama of the scene by placing moving figures diagonally throughout the composition and incorporating strongly contrasting areas of light and shadow. Rubens also applied vivid, rich colors inspired by his study of Venetian painting. He painted broken, agitated brushstrokes, emphasizing the energy of the battle. In his choice of subject matter, Rubens shared with Caravaggio an interest in showing the climax of the story. Baroque painters tried to stimulate viewers by portraying dramatic, exciting action.

Sir Anthony Van Dyck. Rubens operated a large studio in Antwerp and directed a crowd of apprentices and assistants. Among the talented young artists who worked at his studio was Anthony Van Dyck. Van Dyck had already become an accomplished painter when he joined Rubens in 1618 and began producing classical and religious works in imitation of his master. However, Van Dyck wanted to avoid competing with Rubens in the area of history painting, so he turned to painting portraits. Van Dyck moved to Italy in 1621 and dedicated himself to the perfection of court portraiture.

Following a brief return to Antwerp, Van Dyck moved to England in 1632, where he worked for King Charles I in London. Van Dyck established the characteristics of refined court portraiture by stressing the elegance and splendor of the royal family. In Van Dyck's paintings, figures wear lavish costumes and are surrounded by the marks of power and luxury.

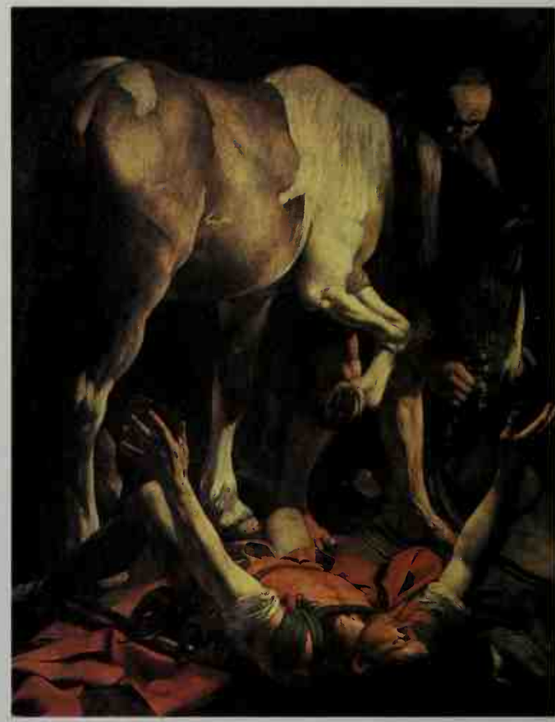
In outdoor scenes, Van Dyck often showed the king on a horse or standing next to his mount. These equestrian portraits refer to the monarch's military skill and political authority. Van Dyck's most famous work is *Portrait of Charles I Hunting* (page 63), a depiction of the English king with his walking cane, his attendant, and his horse. Van Dyck presented an informal portrait of Charles at ease in the countryside. The refinement and grace of the pose, the elongated figure and hands, and the carefully detailed costume all combine to flatter the monarch. Van Dyck also painted the English queen, Henrietta Maria, and the royal children. He was a leader in portraying unassuming, innocent images of children. For other examples of baroque painting, see **Caravaggio, Michelangelo Merisi da; Clothing** (The 1600's); **Daniel, Book of; Jesus Christ** (picture: Jesus's last hours); **Rubens, Peter Paul; Van Dyck, Sir Anthony.**

Classicism. The Roman Catholic Church established the dramatic baroque style in public religious art. In contrast, many private patrons and scholars in Italy and France preferred works that exhibited a balanced, orderly presentation of classical and religious themes. King Louis XIV of France officially embraced this style, known as *classicism.* It became officially approved and encouraged with the establishment of the French Royal Academy of Painting and Sculpture in 1648. Two French artists, Nicolas Poussin and Claude, developed and popularized classicism both in France and in Italy, where they lived and worked.

Poussin differed considerably from the Baroque master Caravaggio in choice of subject matter and style. Caravaggio's dramatic paintings appealed immediately to the viewer's emotions. The composed art of Poussin spoke to the mind and required an intellectual response. Poussin believed the only suitable subjects for art were serious, uplifting stories from classical mythology, ancient history, and Christianity.

Poussin read extensively about his subject matter and then considered how best to tell the story through a painting. He proceeded methodically by carefully preparing sketches and elaborately arranging small wax figures to determine the composition.

Poussin's formal classicism appears in scenes from antiquity as well as in Christian subject matter. In his *Holy Family on the Steps* (page 64), Poussin organized the figures in a triangular arrangement on a stairway. The balanced effect of this composition emphasizes the calm, dignified content of the painting.



Poussin and Claude also stimulated an interest in landscape. The classical French presentation of nature is evident in Claude's *The Father of Psyche Sacrificing at the Temple of Apollo.* The painting appears in the **Classicism** article. The landscape overwhelms the small, unimportant figures in the foreground and points to the establishment of pure landscape as an acceptable subject for painters. The natural lighting and atmospheric

conditions in Claude's landscape paintings are partly based on nature studies in the Italian countryside. However, Claude carefully planned the composition. He refined any imperfections or irregularities in the actual views in his search for an idealized scene. For other examples of classical paintings, see **Mythology** (picture: The Trojan Warrior Aeneas); **Poussin, Nicolas.**

The Dutch masters. During the 1600's, the northern Netherlands, called Holland, prospered as an independent Protestant nation. Holland was a democratic country governed by wealthy bankers, merchants, and traders. Without the patronage of the church or a royal court, Dutch artists depended on the wealthy middle class to buy works of art on the open market.

The Dutch middle class looked for small paintings suitable for private homes, rather than large-scale religious, historical, and mythological works. Local artists responded to the new market demands by specializing in a particular subject, such as still lifes, seascapes, cityscapes, portraits, or genre scenes. Frans Hals perfected portraiture in Haarlem, and Jan Vermeer became a master of genre painting in Delft. Rembrandt painted a wide range of subjects in Amsterdam.

Hals painted individual and group portraits of Dutch men and women from all classes of society. In his *Banquet of Officers of the Civic Guard of Saint George at Haarlem, 1616* (this page), Hals depicted the members of a Dutch national guard celebrating during an annual feast. Earlier group portraits showed figures arranged in rows in stiff positions facing front. Hals's large canvas realistically shows the men in an active, open exchange of gestures and expressions. The excitement and frozen motion of the scene are conveyed by the parted lips, raised glass, and hoisted banners. Loose individual

strokes of paint applied *alla prima* intensify the sense of movement and action.

Hals's imagery reveals the interest of Dutch artists in truthfully capturing the natural appearance of the world. This attention to realism is also evident in the still-life images of Willem Claesz. Heda and the landscape paintings of Jacob van Ruisdael. Heda's *Breakfast Table* (page 64) is a so-called breakfast piece, which featured painstakingly rendered but informally arranged food and dishes. Heda created a sense of luxury through the silver plates, the ornate goblet, and the richly detailed pie.

In his small landscape paintings, Ruisdael recorded recognizable buildings, roads, and landmarks such as windmills. In *The Mill at Wijk* and other works, Ruisdael included anonymous figures engaged in everyday activities to emphasize the commonplace beauty of the setting. This painting appears in the article **Ruisdael, Jacob van.**

Jan Vermeer focused on scenes of everyday life in Delft. Like many other Dutch artists of the 1600's, Vermeer could not earn a living by selling his paintings. He worked as an innkeeper and art dealer to support his family and painted in his deliberate, precise style when he could find time. His small number of works show women at work and play in rooms illuminated by a soft, encompassing light. Sometimes the women are engaged in solitary household chores, such as lacemaking. In other paintings, they entertain visitors in scenes of music making or casual conversation.

In *Young Woman Reading a Letter* (page 66), Vermeer exhibited his interest in the visual effects of light on various surfaces ranging from the creased map on the back wall to the soft, blurred hair surrounding the woman's face. Although Vermeer's paintings seem to record ordinary life, many of his scenes have deeper symbolic significance. For example, maps often refer to the outside, male-dominated world of business in contrast to the interior woman's world of household concerns. The realistic objects in Dutch genre paintings often have hidden symbolic meanings.

Judith Leyster, like Vermeer, specialized in scenes of everyday life. In particular, she painted boisterous scenes of tavern life and pictures of women quietly performing domestic tasks. Leyster's quick, vivid brushstrokes show the influence of Hals, while her use of chiaroscuro reflects the style of Caravaggio.

Rembrandt is the greatest Dutch artist. As a young man, he established his reputation as a portrait painter. At the same time, he depicted scenes from the Bible, classical history, and mythology in Dutch settings. Like Caravaggio, Rembrandt updated the past by showing historical figures in scenes and costumes of his time. As a careful observer of reality, Rembrandt looked to the world around him for his subjects. The resulting realistic scenes were considered crude, vulgar, and unacceptable by many critics.

As a young artist, Rembrandt preferred scenes of action and violence, but in his mature years he chose subjects of inner psychological meaning. In *The Return of the Prodigal Son* (page 65), Rembrandt captured a moment of reflection and meditation in a solemn and sober scene. In this painting of a Biblical parable, the wasteful son is embraced by his loving father in a calm, controlled composition. Rembrandt rendered the scene in

dark earthy tones of brown and red. His subtle shading emphasizes the stillness and serenity of the story. An additional feature of Rembrandt's style is his use of thick layers of paint called *impasto* to create textures on the surface of the canvas. For other examples of Dutch painting of the 1600's, see **Aristotle; Hals, Frans; Jesus Christ** (The Nativity); **Rembrandt; Steen, Jan; Vermeer, Jan; World, History of the** (The Renaissance).

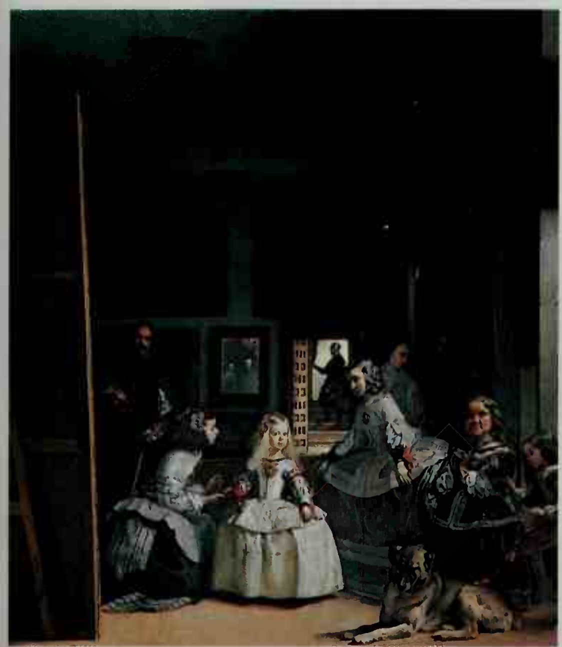
The Spanish masters. The classical themes favored by many Italian and French artists do not appear in the varied production of Spanish painters of the 1600's. Both Jusepe de Ribera and Francisco de Zurbarán depicted religious subjects for the Roman Catholic Church. The most famous Spanish painter, Diego Velázquez, painted royal portraits after an early interest in still life and genre pictures.

The influence of Caravaggio appears in the art of Ribera. He worked in Naples, which was controlled by Spain in the 1600's. There he quickly learned the dramatic realism of Caravaggio's style by studying the Italian's altarpieces in Naples. Ribera depicted the heroism and conviction of ordinary people caught up in extraordinary events. Many of his paintings show Christians becoming martyrs or other intensely powerful images of suffering and hardship.

In the art center of Seville, Francisco de Zurbarán developed a style that incorporated Caravaggio's realism with a native Spanish interest in mysticism. The devout, enthusiastic religious orders of Seville became Zurbarán's chief patrons.

Zurbarán painted *Saint Serapion* (page 63) for the Mercendarian Order of Friars in Seville. The strongly illuminated figure of the saint fills the canvas as his three-quarter-length body is pushed forward toward the viewer. The solid figure of the martyr serves as a solemn and simple focus on devotion and meditation. This mystical and sober quality is Zurbarán's contribution to painting of the 1600's.

In the works of Velázquez, the perfection of a national and individual style appears. Early in his career, Velázquez popularized *bodegones* (kitchen scenes) in which half-length figures are shown eating and cooking in kitchen settings. These paintings include elements of still lifes and are usually marked by vigorous realism and tenebrism.



From 1623 until his death in 1660, Velázquez worked for the Spanish king, Philip IV. He established his international reputation with his royal portraits. Velázquez painted full-length portraits of the king; his wife and children; and his court, including servants, jesters, and dwarfs. In many portraits, Velázquez isolated the figures against a neutral background, focusing the viewer's attention on the face and attitudes of the sitters. In contrast to Van Dyck, Velázquez included few or no attributes of power in his images of Spanish royalty. Instead, Velázquez heightened the casual, unplanned qualities of his portraits by depicting his sitters engaged in everyday activities in informal settings.

Velázquez's mature style is revealed in his master-

piece, a portrait of the royal family in the artist's studio called *Las Meninas (The Maids of Honor,* page 65). This large-scale painting is a portrait of the Princess Margarita Maria. Her royal parents are reflected in the mirror on the back wall. The painter on the left is Velázquez himself. The artist masterfully united real and pictorial space by having the princess look casually out of the composition, presumably toward her parents, who stand in the same position as the viewer.

Velázquez conveyed a strong sense of realism by depicting figures in frozen motion. A sense of informality is created by the poised brush held by the painter, the initial movements of a curtsy by one of the maids, and the playful kick the dwarf gives the dog at the far right. The spontaneity of the portrait is enhanced by the way in which Velázquez suggested, rather than outlined, forms. His broad handling of rough, broken brushstrokes also produces a powerful sense of light and atmosphere throughout the work. For other examples of Spanish painting of the 1600's, see **Greco, El; Moors; Murillo, Bartolomé Esteban; Resurrection; Velázquez, Diego**.

Rococo painting. The rococo style developed in France after the death of Louis XIV in 1715. At that time, aristocrats left the court at Versailles and moved to Paris. There, they became customers for a new style of refined, delicate art that would ornament their city homes. From France, the rococo style spread as an international court style to Germany and Austria. The term *rococo* comes from *rocaille,* the rock and shell designs that decorated the outdoor parks of the French nobility. In rococo interiors, curved, organic designs provided the setting for small, elegant works of art.

Rococo painting had its beginnings in the late baroque period. At the end of the 1600's, the French Academy divided into two opposing groups, the Poussinists and the Rubenists. The Poussinists followed the stylistic characteristics of Nicolas Poussin. They respected classical design, careful contour lines, and uplifting and intellectual subject matter. In the 1700's, the Poussinists were overpowered by the Rubenists, who embraced the rich, colorful, and emotional art of Peter Paul Rubens. French rococo artists adapted the dynamic compositions and energetic brushwork associated with Rubens. These artists painted lighthearted, frivolous subjects, such as courtship, the theater, and games.

Antoine Watteau was an early supporter of the rococo style. He established a new category of painting called the *fête galante,* which loosely refers to scenes of couples courting in outdoor settings. In Watteau's *The Island of Cythera* (also known as *The Embarkation for Cythera,* page 66), a hazy landscape of pastel colors provides the setting for slender, graceful men and women. They stand on the shore of the island of Aphrodite, the Greek goddess of love. Watteau refined Rubens's robust colors by applying a pearly white underpaint that glows through the blues, reds, and greens of his figures and landscape. Watteau's loose handling of paint builds indistinct outlines throughout the composition, heightening the sense of light and movement.

Elisabeth Vigée-Lebrun was one of the most fashionable French painters of the rococo period. She painted attractive, flattering portraits, devoting much attention to rich fabrics and fine clothes. Vigée-Lebrun's subjects included members of the French royal family as well as important members of French society.

François Boucher was Watteau's successor. Boucher continued the rococo style by painting cheerful mytho-

logical scenes and informal portraits for the French aristocracy. As a popular painter of the French court, Boucher depicted a wide range of themes in his graceful, delicate style.

Jean Honoré Fragonard, a pupil of Boucher, was the last great rococo painter. Working during the mature period of rococo art, he continued the formal characteristics of this charming style in *Bathers* (page 67). This painting was inspired by the colors of Rubens and the technique of Frans Hals. *Bathers* shows the rococo preference for playful themes of love. Fragonard's broken brushstrokes suggest, rather than define, the glowing bodies of nude women bathing in a frothy pond. For another example of rococo painting, see **Boucher, François.**

Neoclassicism refers to a severe style that developed in France at the end of the 1700's in reaction to the playful quality of rococo art. Neoclassicism dominated French art from the late 1700's to the early 1800's. It signaled a return to the art of Poussin and the French Academy style of the 1600's. Stylistically, neoclassical artists valued the formal elements of line and form over color. They considered the proper subjects for art to be moralizing themes of grand historical significance.

In addition to the influence of Poussin, neoclassical artists were inspired by discoveries at the ancient Roman cities of Pompeii and Herculaneum. The ruins of the cities were excavated in the 1700's after lying buried in volcanic debris for hundreds of years. Excavations there revealed for the first time actual archaeological

evidence of the interiors, clothing, and lifestyles of classical antiquity.

Jacques Louis David was the leader of the neoclassical movement. He returned to the serious academic traditions that dominated French painting before the lighthearted rococo age. In *The Oath of the Horatii* (this page), David painted a straightforward story without distracting details. The clothing and architecture are based on actual historical examples from Roman antiquity. The monumental figures are arranged in rigid poses across a shallow space in imitation of sculptural decorations called *friezes* found in classical buildings. In the stagelike setting of the painting, the harsh lighting and cool colors emphasize the crisp, hard outlines that define the forms in the composition. The surface of the painting is smooth and highly finished, emphasizing the firmly modeled forms. Brushwork is rarely visible. For examples of neoclassical painting, see **Clothing** (The 1700's); **David, Jacques Louis; French Revolution** (picture: The death of Marat); **Socrates.**

The 1800's

By 1820, an increasing number of artists came to consider neoclassicism old-fashioned and no longer meaningful. However, its influence lasted into the 1890's, particularly in France. This influence resulted from the fact that many artists from Europe and the United States went to Paris to study. They enrolled at the state-sponsored École des Beaux-Arts (School of Fine Arts). The school became the most important art school in the Western world and the model for most art schools in the 1800's. Most students also received private art training in Paris. Both art schools and private teachers based their instruction on neoclassical principles until the early 1900's. The term *academic* has been applied to those artists who followed the conservative ideals taught at the art schools of the 1800's.

Most academic teachers of art in Paris taught their students that history, including mythology and the Bible, provided the most significant subject matter. From the academy's point of view, any other subject matter lacked important moral or political meaning. Students learned to emphasize drawing and carefully composed compositions rather than brushwork, color, and natural impulses. Adventurous artists of the later 1800's received unfavorable reviews of their work. Exhibition juries rejected paintings by artists whose style and subject matter did not meet the rules of academic art.

Later neoclassicism. From the 1820's to the 1860's, the French painter Jean Auguste Dominique Ingres was the most famous neoclassical artist. He departed from

earlier neoclassical ideals by rejecting the principle that art had to preach a strong message. But he did argue that artists should paint historical scenes and that all art should be based upon skillful drawing. His smoothly painted, idealized portrait *Comtesse d'Haussonville* (page 71) demonstrates one of the many ways the neoclassical style continued after the time of David.

A late flowering of the neoclassical tradition occurred in England from the 1860's to the 1890's. Such artists as Sir Lawrence Alma-Tadema, Lord Frederic Leighton, and Sir Edward Poynter painted romantic visions of the classical past.

Romanticism was the major new trend in the arts of the early 1800's. Unlike neoclassicism, romantic art was not linked by subject matter or style. The unifying element among romantics was a common desire to express the individual's innermost beliefs, feelings, or emotions. The search for a personal inner voice was often expressed in self-portraits.

The romantics also made an important contribution to painting by popularizing landscapes. The academic system shunned landscape painting. The academic avoidance of landscape actually proved an advantage to the romantics, allowing them to experiment in an area where few rules existed.

The German artist Caspar David Friedrich painted some of the most powerful and mystical landscapes of the romantic period. A typical example is *Village Landscape in the Morning Light* (page 69). Friedrich was deeply patriotic and religious. He believed that only through landscape could he capture his most personal feelings regarding his love for his country and his belief that God was most closely felt in nature. Friedrich's paintings are based upon careful studies of the natural world. However, his works are filled with a mysterious, otherworldly quality that goes beyond nature and demands a strong emotional response from the viewer.

The English artist John Constable also explored the new freedom of self-expression through landscape painting. Constable felt a deep love for the landscape and lifestyle of Suffolk in eastern England, where he grew up. To express this strong attachment, he portrayed a quiet, lush, and beautiful Suffolk landscape. There everyone, including children and laborers, lived in harmony with the bountiful land and with God. Constable expressed many of these ideals in *Boat-Building near Flatford Mill* (page 69). The rough brushstrokes and broken color capture a feeling of air, light, and wind.

Constable's approach to painting created a sense of real living nature that influenced romantic painters in France, particularly Camille Corot and the Barbizon School, led by Jean François Millet and Théodore Rousseau. These artists captured the simple beauty of the countryside around the village of Barbizon, near Paris. Their paintings often stress the strong bonds between the peasants and their environment. Of these artists, Millet particularly emphasized the difficult but pious life of the hard-working French peasants.

In contrast to the work of Constable or the Barbizon School, J. M. W. Turner of England took a different approach to the study of nature. His late work in particular explores in a personal way the strong effects of color and atmosphere. Turner preferred warm colors, swirling paint, and light that seems to dissolve forms. He created an emotional interpretation of the power and mystery of nature that is far more troubling than the work of other landscape painters of his time. A good example of this more pessimistic vision of nature is his *Snowstorm: Steamboat off a Harbour's Mouth* (page 71). For all its brilliant and beautiful effects of light, the painting presents the viewer with a vision of humanity unable to control the forces of nature.

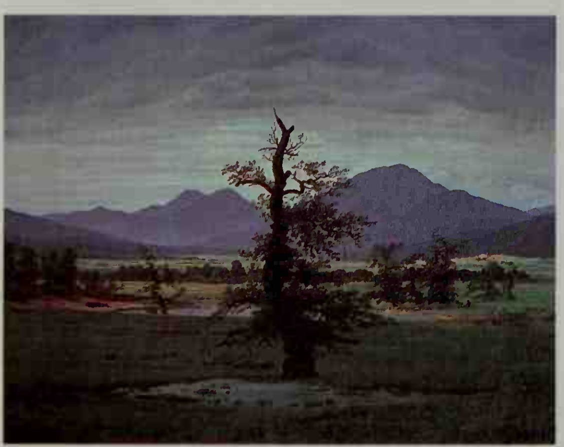
The romantic notion that one must deal with one's innermost fears and thoughts is perhaps most often found in the work of the Spanish artist Francisco Goya. As he grew older, Goya became increasingly depressed and discouraged about his own life and humanity in general. Goya was one of the first artists to persistently explore the dark side of the human mind. Some of his work evokes a disturbing nightmare full of haunting thoughts about life and war.



Romantic artists were among the first to feel it was the artist's responsibility to respond to events of their day. After witnessing the horrors of the French occupation of Spain that began in 1808, Goya painted his famous *The Executions of 3rd May, 1808* (page 68). The painting shows the cold-blooded execution of several Spaniards suspected of participating in an uprising against the French. Goya portrayed faceless, anonymous French soldiers who methodically shoot the civilians. For the first time, an artist made a modern statement about war, emphasizing not heroes but helpless victims. The strongly contrasted lights and darks and the rich, loose brushwork add to the emotional impact of the work. Goya was telling the viewer that war is a senseless, brutal act. He dealt even more honestly and graphically with the darker sides of war in his series of etchings the *Disasters of War.*

In France, the first two major romantic artists were Théodore Géricault and Eugène Delacroix. Géricault's *The Raft of the Medusa* (this page) deals with an event of his time, the horrible suffering of survivors of the wreck of a French ship off west Africa in 1816. In contrast to the neoclassical style, Géricault's brushwork, color, and lighting produce an intensely emotional reaction from the viewer.

Like many other romantics, Delacroix was fascinated with non-Western cultures. He was particularly attracted to the Middle East, where France was establishing colonies. His *The Women of Algiers* (this page) is a typical Western fantasy of another culture in the early 1800's. Delacroix portrayed beautiful women and exotic clothing, accessories, and architecture, creating a sense of mood and mystery through the use of deep shadow. Art for a new public. By the 1830's, growing numbers of artists were creating works meant to appeal to a new art audience. This audience consisted of the unsophisticated but enthusiastic European middle class. These people attended art exhibitions in rapidly increasing numbers.

The Old Shepherd's Chief Mourner by Sir Edwin Landseer
1837. Oil on canvas. 18 by 24 in. (46 by 61 cm).

Some artists, such as Paul Delaroche of France, painted sentimental historical scenes. Other painters, including Sir David Wilkie of Scotland and Sir Edwin Landseer of England, concentrated on storytelling or sentimental scenes of everyday life in addition to historical painting. Landseer's *The Old Shepherd's Chief Mourner* (this page) is a typical example of pictures that appealed to the new popular taste. The painting shows a sad dog, the only mourner at the draped coffin of its master, surrounded by the remains of their humble but happy existence.

Realism. By the late 1840's, an increasing number of painters believed that artists should focus on the life of their day, presenting it in an accurate and objective manner. Scenes of everyday life did appear in art of the early 1800's, but the subject became the dominant trend from about 1850 to the end of the 1890's. Artists who specialized in creating scenes of daily life are now called *realists.*

The most famous and innovative realist painter was Gustave Courbet of France. Courbet argued that artists must paint scenes of everyday life taken only from their personal experiences. They should present the subjects in a style that would convince the viewer that the event had actually happened in the manner the artist showed it.

Courbet's *The Stonebreakers* (page 72) shows a young boy and an old man earning a living at the exhausting and low-paying job of breaking stones. As a realist, Courbet's approach to the subject differs greatly from that of earlier artists. For example, Landseer would have emphasized the storytelling aspects of the scene and made it more emotional. Courbet's loose style of painting, with its gritty earth tones, downplays these two ele-

ments. The painting illustrates how Courbet broke with both the French neoclassical and romantic traditions by limiting himself to seemingly objective views of daily life.

The impact of Courbet in France was tremendous. Academic artists called his work crude, vulgar, and pointless. But many young painters in Paris immediately began to portray scenes of modern life in an honest and unsentimental fashion. For another example of realist art, see the article **Courbet, Gustave.**

The Pre-Raphaelite Brotherhood was a group of English painters founded in 1848 who were influenced by both romanticism and realism. They called themselves Pre-Raphaelites because they wanted to revive the purity and sincerity they saw in Italian art before Raphael. The leading Pre-Raphaelite painters were William Holman Hunt, Sir John Everett Millais, and Dante Gabriel Rossetti. Many of their works deal with everyday life, such as scenes of woodcutters, roadbuilders, poor children, and young lovers. Other works deal with the Bible and literature.

Whatever their subject, many of the Pre-Raphaelites painted in great detail, often copied literally from nature. Millais's *Ophelia* (page 73) is based upon a character from William Shakespeare's *Hamlet.* Millais showed Ophelia slowly drowning after she had been driven out of her mind by her father's death and Hamlet's cruel rejection of her love. The idea for the painting comes from literature, but the method was based on the careful study of real life. The artist actually had a model wear an antique dress and pose floating in a heated bathtub. The choice of colors was unusually vivid as the artist attempted to copy actual sunlight. Many Pre-Raphaelite landscapes capture a sense of brilliant light as effectively as the impressionist painters did 10 or 20 years later.

The combination of close observation of nature and imaginary events frequently gives an odd feeling to Pre-Raphaelite paintings. Inspired by Rossetti, many later Pre-Raphaelite artists, such as Sir Edward Burne-Jones, preferred to abandon the study of nature for a more dreamlike vision of the past. For another example of Pre-Raphaelite painting, see **Rossetti, Dante Gabriel.**

Edouard Manet and the impressionists. The early French realists concentrated on scenes of country life. However, beginning in the 1860's, Edouard Manet and other French artists of his time began to focus on urban themes. Manet's *Music in the Tuileries Gardens* (page 74) successfully captures a sense of the newly leisured middle classes relaxing and listening to music in a park near the Louvre museum in Paris.

Manet included little detail in his paintings and did not carefully model his figures. He believed that his apparently rapid, impulsive brushwork would convince the viewers they were looking at a scene actually observed by the artist. The French art establishment attacked Manet's everyday subject matter and his sketchy style. As a result, the public rarely saw his art during his lifetime.

Manet's approach to art had a major influence on a group of art students of the 1860's who later became known as the *impressionists.* They agreed with Manet's insistence that artists portray the experience of average city dwellers in a natural, unplanned style. Such a style, they believed, captured the movement and energy of their age.

The impressionists initially included Edgar Degas, Claude Monet, Camille Pissarro, Pierre Auguste Renoir, and Alfred Sisley. They were eventually joined by such artists as Mary Cassatt, Berthe Morisot, and Gustave Caillebotte. All were influenced by French and English romantics as well as realists, but they admired no artist

more than Manet. In the 1870's, he in turn would be inspired by these younger artists.

In most impressionist pictures, the figures are ordinary middle-class city dwellers like the artists. The paintings celebrated the Paris of grand boulevards and exciting night life. Even when the impressionists painted village and riverbank scenes, they usually showed the weekend activities of Parisians taking day trips into the nearby countryside. An example is Renoir's *The Luncheon of the Boating Party,* which appears in the article **Renoir, Pierre Auguste.**

Some impressionists, including Degas, Cassatt, and Caillebotte, preferred to work traditionally, basing their final paintings on drawings or studies. However, most impressionist artists developed a revolutionary style that involved working directly from their subject, not from preparatory studies. For example, in his *Two Sisters,* Renoir applied the brushwork quickly and thickly. The colors are extremely bright, and the modeling of the forms is not emphasized. This painting appears in the **Impressionism** article.

As a result of years of carefully studying nature, the impressionists produced paintings full of sparkling light, shimmering water, and other effects never before seen in art. Whether in city or rural scenes, the human figures are portrayed in harmony with their environment. Never previously had the passing or momentary qualities of nature and human activities been captured so convincingly. For other examples of paintings by Manet and the impressionists, see **Manet, Edouard; Alabama** (ship); **Monet, Claude; Morisot, Berthe; Pissarro, Camille.**

New visual sources. The work of the French realists and impressionists looks far different from the paintings created earlier in the 1800's, largely because of the impact of new visual sources. The desire to make things look "objectively real" occurred in the years just after photography became available to the public. Some of the impressionists' freshest and most creative ideas may have come from looking at photographs. These ideas include figures cut off at the edge of the painting, unbalanced compositions, and blurred figures. *The Dancing Class* by Edgar Degas is an example. It appears in the article **Degas, Edgar.**

The impressionists and other artists also took their subject matter from illustrations published in popular magazines of the day. In addition, Japanese prints, collected by Manet and other artists, played a central role in art of the later 1800's. These prints emphasized cut-off figures and unusual compositions, scenes viewed from above, flat and unmodeled forms, and bright colors. Several of Mary Cassatt's paintings, including *The Bath,* are brilliant reinterpretations of ideas she gained from studying Japanese art. The painting appears in the article **Cassatt, Mary.** The concept of looking at non-Western sources for fresh ideas would become increasingly popular during the late 1800's and early 1900's.

Painting outside France. Realism was the most popular art movement from about 1850 to 1900. In England, the leading realist painter was William Powell Frith. During the 1850's and 1860's, he painted vast crowd scenes that portrayed the action of people from many walks of life. Even French academic artists, including James Tissot, portrayed the life of their times. Some of Tissot's pictures poke fun at the attitudes of the newly rich in London who were trying to learn how to act in high society.

Some realists had important comments to make about society. In Russia, a group of artists called the Wanderers created works that toured from city to city. The paintings dealt with the chief problems of the day, including poverty, lack of education, and poor medical care. To these painters, artistic issues were secondary to their desire for reform that would correct social injustice. Many paintings of Ilya Repin portray the hard life of peasants. In England, such young artists as Sir Luke Fildes, Sir Hubert von Herkomer, and Frank Holl portrayed the difficult condition of the homeless, the elderly, and strikers. These artists are now called *social realists.*

Realism was also popular in the United States. Winslow Homer created memorable scenes of everyday life

of New Englanders and Maine fishing crews. Thomas Eakins returned to Philadelphia after learning neoclassical techniques in Paris to create powerful realist portraits. An example is his portrait of poet Walt Whitman in the article **Whitman, Walt.** The African American artist Henry Ossawa Tanner, a student of Eakins, subtly captured the spiritual side of a humble family in *The Thankful Poor* (page 76).

The international impact of impressionism was not felt until the 1890's and early 1900's. By then, followers of French impressionism could be found throughout the world. Besides the American-born Mary Cassatt, the most famous American impressionist was Childe Hassam. However, many young artists did not really understand impressionism, equating it simply with middle-class subject matter, bright colors, and loose brushwork.

The art world, 1850-1900. During the later 1800's, art enjoyed unprecedented popularity. Each year, thousands of visitors attended exhibitions of new artworks held in most Western European countries. The two most famous were the Salon exhibition in Paris and the Royal Academy of Arts exhibition in London. Enthusiastic visitors went to these shows to be instructed and entertained. In the days before motion pictures or television, no other medium had the impact of painting. Viewers could see history come alive in the works of Ingres and Alma-Tadema. Beautiful landscapes with happy peasants and contented animals satisfied the nostalgic needs of the city dwellers. Genre scenes by Frith or the impressionists captured everyday middle-class urban existence in all its variety. Some paintings were so popular that railings had to be placed in front of them to keep the audiences from getting too close.

Popular artists, such as Alma-Tadema and the French academic painter William Bouguereau, became millionaires. They enjoyed fame and social status rivaling today's movie stars. They made vast sums of money not only from their paintings but also from the sale of engravings that reproduced their work.

The profits to be made from art led to an increasingly important role for art dealers. Art critics also began to play an essential part for the first time. Many exhibition visitors felt they lacked the necessary understanding of art to absorb the thousands of works in the large exhibitions. They looked to the critics for guidance. Many critics wrote for art magazines, another popular way people learned about art.

Women artists. Unprecedented numbers of women became painters during the 1800's, but they rarely enjoyed the success and popularity of male artists. This inequality resulted from several factors. Women were not allowed into the best art schools, primarily because it was considered improper for women to study and paint a nude model. Thus, women lacked the necessary training to compete with men in the area most admired in the academic world, figurative and historical painting. This exclusion also kept women from making the political and social contacts necessary to succeed in the competitive art world.

The English painter Emily Osborn explored the difficulties faced by women attempting to break into the man's world of art in *Nameless and Friendless* (this page). The painting shows a poor young woman, apparently a widow, finding her art treated with disdain by a pompous male art dealer. The gaze of the two men watching at the far right implies that they admire her as a beautiful woman but do not take her seriously as a creative artist.

Young female art students believed they lived in a promising period in spite of the many difficulties they were forced to overcome. Private coeducational art schools were common, as were schools for women only. But even these schools would not allow women to work from nude models until the turn of the century. The large national exhibitions exhibited many works by women, partly because entries were submitted anonymously. By the mid-1800's, women also began to hold their own private exhibitions.

The most significant show of women's art in the 1800's was held at the Chicago World's Columbian Exposition in 1893. Mary Cassatt painted the mural *Modern Woman* especially for the Women's Building. Women also showed their work by joining movements or groups of male artists who were treated as outsiders because of the radical nature of their art. For example, both Cassatt and Berthe Morisot played central roles in impression-

ism when that movement was scorned by the art establishment.

The most famous woman artist of the 1800's was the French painter Rosa Bonheur. The sale of her paintings and the engravings of her pictures enabled her to live in a grand château in the countryside near Paris. Bonheur specialized in animal paintings. Her best-known work was *The Horse Fair,* which appears in the article **Bonheur, Rosa**. Animal themes were popular in the 1800's, and only Sir Edwin Landseer of England was considered Bonheur's rival. Bonheur had the ability to portray beautiful, majestic, and spirited animals. She often showed animals playing an essential part in agriculture, generally working in harmony with people, and at times displaying human emotions.

In England, Elizabeth Thompson (who later became Lady Butler) was the only woman painter who matched Bonheur's fame. Thompson was the first woman artist to succeed in military painting. Her painting *Calling the Roll After an Engagement, Crimea* (this page) was one of the most popular pictures ever exhibited in a Royal Academy show, and was purchased by Queen Victoria. Thompson's subject is the aftermath of a hard-fought battle between the English and the Russians during the Crimean War of the 1850's. She did not focus on the glories of victory. Instead, she presented a close-up look at

the emotional and physical exhaustion of the soldiers as they struggled to answer roll call. Her gritty realism became immediately popular, because never before had the British public been so exposed to the true nature of war.

Today, the impressionist painters Mary Cassatt and Berthe Morisot are the most popular female artists of the 1800's. Both organized and participated in group exhibitions and helped sell impressionist works to rich friends. Their art differs from that of male artists in its emphasis on the daily lives of middle-class women. Cassatt and Morisot especially painted the domestic existence of these women, often focusing on themes of parents and children. For examples of their domestic themes, see **Cassatt, Mary; Morisot, Berthe.** The two women also painted scenes of their summer vacations as well as their urban lives, such as riding in carriages or attending the opera.

Postimpressionism. Unlike impressionism, postimpressionism was not a movement of artists working toward similar goals. The term has been used to refer to several artists who were influenced or taught by the impressionists, but who later rejected or modified that group's ideas. The postimpressionist painters, with their varying styles, now are among the most admired figures in the history of art.

The postimpressionists were little known during their lifetimes, but shortly after their deaths they had a tremendous impact on the young experimental artists of the early 1900's. The most influential postimpressionists were Paul Cézanne, Paul Gauguin, Georges Seurat, Henri de Toulouse-Lautrec, and Vincent van Gogh.

Cézanne painted landscapes that stressed what he felt was lacking in the impressionist approach—form and mass. In addition, his still lifes and portraits had a huge impact on artists of the early 1900's. For example, *Still Life with Commode* (this page) taught the cubist artists Pablo Picasso and Georges Braque that space and perspective could be manipulated in any way the painter chose.

Both Gauguin and van Gogh wanted to express their innermost feelings through their art. *The Starry Night* (page 39) shows how van Gogh achieved this goal through his use of intensely brilliant color; thick, rapidly applied brushstrokes; and expressive line. Few artists have been able to equal the passionate intensity of his paintings, which he filled with both hope and pain. Van Gogh's choices of color and subject matter often had an emotional and personal meaning for him. He was a key influence on the Norwegian artist Edvard Munch and, through Munch, the German expressionist painters of the early 1900's.

Gauguin was a friend of van Gogh, but he explored his personal feelings in a different way, as can be seen in his *The Vision After the Sermon* (also called *Jacob Wrestling with the Angel,* this page). Gauguin had first painted in an impressionist style. However, in *The Vision After the Sermon,* he developed a style that enabled him to create a clearly symbolic image rather than a lifelike study of nature. The painting represents the thoughts or imaginings of peasants in the French province of Brittany after hearing a sermon about the Biblical story of Jacob wrestling an angel. Using flat, bold colors and strong patterns, Gauguin creates a dreamlike vision far removed from the everyday world.

Like much of Gauguin's work, *The Vision After the Sermon* provokes more questions in the mind of the viewer than it answers. Gauguin would later search for purity and simplicity in both his life and his art by settling on the island of Tahiti.

Toulouse-Lautrec is best known for his paintings and lithographs of Parisian night life in the 1880's and 1890's. He painted scenes of Paris cabarets and music halls as well as portraits of dancers, singers, clowns, and prostitutes. Toulouse-Lautrec was strongly influenced by Edgar Degas and Japanese prints. He was a master at capturing movement. His forms were flat with curved lines. Many of his scenes of night life were energized by bright colors, vivid lighting, and strong contours. An example is *At the Moulin Rouge,* which appears in the article **Toulouse-Lautrec, Henri de.** He painted many of his oils on unprimed cardboard, so that the neutral whitish color of the board became part of the design.

Georges Seurat created a style of painting variously

called *pointillism, neoimpressionism,* or *divisionism.* The most famous example of this style is *Sunday Afternoon on the Island of La Grande Jatte* (page 29). Seurat believed that by using an organized color system of carefully placed contrasting dots, he could create works that would glow with intensity when viewed from a distance. Seurat also wished to restore to the human figure a stronger sense of solidity than the figures found in impressionist paintings. The strange stiffness of Seurat's human figures suggests that his silhouettes may have been partially inspired by Egyptian art.

Traditionally, *La Grande Jatte* has been interpreted as a picture of working-class and middle-class people enjoying a Sunday afternoon of relaxation. However, some modern art historians have called attention to the fact that nobody is outwardly happy, no figure looks at any other figure, and few people interact. These historians claim that Seurat actually meant the painting to condemn the impersonal society of the late 1800's. For other examples of postimpressionist painting, see **Cézanne, Paul; Gauguin, Paul; Postimpressionism; Van Gogh, Vincent.**

Symbolism. The symbolists were an international group that flourished particularly in the 1890's. Like the works of the romantics, the art of the symbolists varies tremendously in both style and subject matter. Generally, symbolist painting reflects a growing demand for more spiritual, emotional, and personal approaches to art in a period dominated by realism and impressionism. From these viewpoints, Gauguin is often called a symbolist, as are some other postimpressionist artists. The writings of symbolist authors inspired many young artists. So did the fantasies painted by such older artists as Dante Gabriel Rossetti and Sir Edward Burne-Jones in England and Gustave Moreau and Odilon Redon in France.

Many symbolists were unhappy with the nature of capitalist urban society in the late 1800's. They objected to such social ills as poverty amid great wealth, pollution, and the shallow values they saw in the middle class. They were also unhappy with how industrial development and new technologies were altering society. Because the symbolists were displeased with the everyday world around them, they retreated inward, preferring to deal with their own personal feelings and interests. Because symbolist art was not appreciated in conservative circles, many symbolists formed groups and held their own exhibitions.

No symbolist better expressed the anxieties felt during the late 1800's than Edvard Munch of Norway. His haunting painting *The Scream* portrays the inner turmoil so many people felt. The painting's composition seems to endlessly echo the isolated figure's cry of fear and loneliness. The work appears in the article **Munch, Edvard.** For another example of Munch's vision of human isolation, see **Norway** (Way of life).

The 1890's were also a period when many men were confused about the changing roles of women in Western society. Women were demanding and slowly gaining increased political, social, and sexual rights and power. Many men observed these changes between the sexes with fear and uncertainty. In reaction, some male symbolist artists painted images of women who were both beautiful and dangerous, sometimes deadly, to men. An example is *Judith with the Head of Holofernes* (page 77) by the Austrian symbolist Gustav Klimt. The artist based the scene on a Biblical story about a woman who saves her town by beheading the leader of a besieging army. For an example of symbolist painting, see **Prometheus.**

Legacy of the 1800's. The art world of the 1800's ended in great confusion and excitement. Many of the

old pictorial traditions popular since the Renaissance were coming to an end. These traditions included deep logical space, linear perspective, and carefully modeled forms. Artists of the later 1800's engaged in experiments with space, two-dimensional forms, and the personal and expressive use of color, brushwork, and line. Because of the efforts, inspiration, and doubts of many artists of the late 1800's, the early 1900's would prove to be one of the most important and innovative periods in art history.

The 1900's in Europe

The Fauves. By the year 1900, a new approach to painting had become established in France. This new approach included the work of the impressionists and postimpressionists. One artist who became interested in postimpressionist painting was Henri Matisse. In the fall of 1905, Matisse exhibited a number of bold, colorful pictures at the Salon d'Automne, a famous exhibition in Paris. He was joined by several friends and colleagues, including André Derain, Albert Marquet, and Maurice de Vlaminck. One critic who saw this exhibition referred to the artists as the *fauves* (wild beasts). This term became the name of the first major art movement of the new century.

Loosely defined, the Fauve style consisted of painting that portrayed simplified views of nature filled with pure, concentrated color applied with rapid brushstrokes. There was little mixing of raw pigment and almost no modeling or shades of color.

The Fauves disbanded in 1907, and the artists continued to develop separately many of the ideas they had shared as a group. After 1907, Matisse moved away from art that represented nature into art that was more idealized and abstract. His *The Dance I* (page 78) employs a radical reduction of all pictorial techniques. There is less attention to drawing, spatial construction, and surface texture. What does emerge in *The Dance I* is the intense color, which became exaggeratedly expressive as Matisse abandoned the brushwork of his earlier Fauve canvases. For other examples of Fauve painting, see **Derain, André; Fauves; Matisse, Henri; Rouault, Georges.**

Cubism, like the Fauves, was a movement that grew out of the influence of postimpressionism. But the cubist paintings of Pablo Picasso and Georges Braque, the leading cubists, were far different from the Fauve works of Henri Matisse. Picasso and Braque indicated a new set of goals for what painting might achieve in the 1900's.

Picasso was born in Spain but settled in Paris in the early 1900's. His first works were heavily influenced by the French symbolists. In paintings such as *The Old Guitarist,* which appears in the **Color** article, Picasso used mainly blue tones. Blue colors dominate in other Picasso works of this time, known as the artist's "blue period." The blue paintings are marked by a melancholy feeling, portraying such subjects as beggars, the homeless, and starving children.

Picasso's blue period lasted more than three years and was followed by the "rose period," which emphasized rose-colored pigments. Picasso abandoned this style in 1907 when he began exploring his interest in so-called "primitive" sculpture from such non-Western lands as Africa and the Pacific Islands.

Perhaps Picasso's most famous painting is *Les Demoiselles d'Avignon,* which appears in the **Cubism** article. Picasso began the painting out of an impulse to combine the classical sculpture of the pre-Roman Iberian culture (present-day Spain and Portugal) with the raw, expressive power of African masks. The painting shows the interior of a house of prostitution in Barcelona, Spain. Five female nudes, two with faces that resemble African masks, stand in a shallow space in front of a curtain. Picasso communicated a psychologically tense experience through crude brushwork and deliberate distortions of drawing and perspective.

From 1909 to the outbreak of World War I in 1914, Picasso and Georges Braque established the basic images and artistic principles that resulted in the birth and development of cubism. Other cubist painters included Juan Gris of Spain and Fernand Léger of France.

Cubism was not so much an art of cubes as of planes. The artist assembled these planes from multiple perspectives that present the many aspects of a subject all at once. In Braque's *Violin and Palette* (this page), the forms of a violin and an artist's palette are displayed as though the viewer were looking at them from many different perspectives at once. The forms melt into one another, discouraging the eye from resting on any one part of the canvas. This early phase of cubism is called *analytic cubism.* The goal of analytic cubism was to examine form and matter, to break them down into their essential elements, and then to reassemble them in a new way. Another example is Braque's *Man with a Guitar,* which appears in the **Cubism** article.

Primarily, Picasso wanted to collect the objects of everyday life and reassemble them in a nontraditional manner that would shock and disturb the viewer. This new way of depicting commonplace subject matter developed even more intensively during the second stage of Picasso's and Braque's cubist work from 1912 to 1914. This period saw the birth of *synthetic cubism,* in which the artist accumulated a range of purely pictorial elements and combined them to create a new form. Such elements typically consisted of everyday materials, such as pieces of newspaper and bottle labels. Picasso and Braque adopted nontraditional methods to construct their cubist images. One popular method was *collage,* in which the artist glued bits of paper and other materials onto the painting. An example of collage is Juan Gris's *The Bottle of Banyuls,* which appears in the **Cubism** article.

Cubism was hailed throughout the world as a symbol for all that was truly advanced and modern in art. For years, all kinds of modern painting were labeled *cubist* simply because they did not concern themselves with representing real objects in the external world.

Expressionism was a movement in the early 1900's that emphasized strong emotional content. Like the romantic movement of the 1800's, expressionism valued personal vision and spiritual revelation. Matisse's use of color to evoke feelings in the viewer is a type of expressionism. His use of color connected him with artists of the previous generation such as Vincent van Gogh and Edvard Munch. All three artists were influential figures in Germany during the early 1900's, where expressionism developed.

What is usually called *German expressionism* consists of two groups of artists who worked in Germany between 1905 and 1914. One was called *Die Brücke* (The Bridge), and the other was *Der Blaue Reiter* (The Blue Rider).

The Bridge group formed in 1905 in Dresden. It gained its name from the group's goal of bridging all the revolutionary elements of culture. The Bridge conceived of itself as both a return to the cooperative craft guilds of the Middle Ages and as a modern approach to making art. The Bridge artists included Ernst Ludwig Kirchner, Karl Schmidt-Rottluff, Erich Heckel, and Emil Nolde. These artists sought to be honest, direct, and interested in spiritual things. They were influenced by the Fauves as well as the art of African peoples, Pacific Islanders, and American Indians.

Kirchner was the leader of The Bridge. His painting is typical of the group's work in its combination of height-

ened emotional intensity, symbolism, and decorative patterns. Kirchner's *Friedrichstrasse, Berlin* shows a dependency on French art in the choice of color and composition. However, the picture contains an emotional vitality characteristic of German expressionism. *Friedrichstrasse, Berlin* appears in the **Expressionism** article.

Another painting by Kirchner, *Street, Dresden* (this page) is a further example of the emotional intensity of the German expressionist style. Kirchner employed jarring contrasts of color, jagged brushstrokes, and deliberate distortion of the figures. These elements combine to achieve a new and transformed vision of the subject matter.

While The Bridge developed in Dresden, another highly influential movement of German painting developed in 1911 in Munich in The Blue Rider. The artists in the group included the Russian-born Wassily Kandinsky, Gabriele Münter, Franz Marc, and the American-born Lyonel Feininger. The Bridge sought to evoke emotional intensity through distorted figures and thick paint. The artists who formed the Blue Rider movement stressed the spiritual and symbolic properties of both natural and abstract forms.

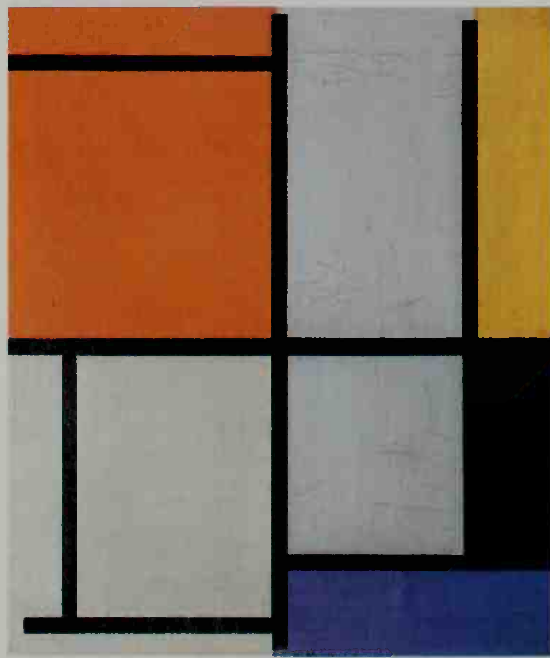
The artistic goals of The Blue Rider artists involved expressing a general disillusionment with the values of society. The group sought a marriage of spiritual and symbolic values in nature. Franz Marc used animal themes. In his painting *The Large Blue Horses,* Marc tried to portray his religious feelings through animal forms. For Marc, the animals he depicted were heroic alternatives to what he believed were the spiritually weakened men and women of his society. *The Large Blue Horses* appears in **Germany** (Arts).

Wassily Kandinsky was the guiding personality of The Blue Rider. He spent several years before 1911 painting works filled with vivid colors influenced by the Fauves. Gradually, Kandinsky's works became abstract. He created an artistic vocabulary of forms and colors that are expressive but do not refer to anything in the physical world. In his *Black Lines* (page 80), there is no longer any form that viewers can recognize as resembling objects in the external world. This type of work is called *nonobjective.* Another example of this artist's nonobjective style, titled *Calm, No. 357,* appears in the **Kandinsky, Wassily** article.

Nonobjective painting in Russia. Perhaps the most durable legacy of cubism was its impact on entirely nonobjective art. Such art first appeared between 1910 and 1920, mainly in Russia and then the Netherlands. Russia's Kandinsky had been the first artist to introduce a completely nonobjective style. With the beginning of World War I in 1914, Kandinsky left Germany and returned to Russia, bringing the most advanced ideas from Western Europe with him.

The prewar period in Russia is notable for the number and quality of women painters. Natalia Goncharova worked closely with artist Mikhail Larionov in a style they called *rayonism.* It developed as a colorful, highly personal version of cubism, but one that remained largely abstract. Liubov Popova was a Russian cubist who worked in France during the prewar years and became one of the strongest followers of Picasso and Braque. Her cubist paintings were more dramatic and energetic than the French version.

Kasimir Malevich became a leader of Russian nonobjective art. He found what he believed was the logical and inevitable conclusion toward which European art was moving. "I fled to the form of the Square," Malevich wrote, "to free art from the [weight] of the objective world."



Malevich's focus on the square resulted in a style called *suprematism.* Malevich's paintings assemble

plane forms together to create floating images. In one painting from his *Suprematist Painting* series (page 81), a black rectangle is poised over a red rectangle. For Malevich, four-sided figures represented the most profound images in art. Malevich believed such shapes replaced the commonplace objects of the everyday world to form an artistic "blueprint" for an ideal world and for superior expression.

Malevich's purely geometric abstract style was at the heart of a nonobjective art movement that swept westward from Russia after World War I ended in 1918. It combined with the principles of a Dutch group called *De Stijl* to influence generations of artists throughout the remainder of the 1900's.

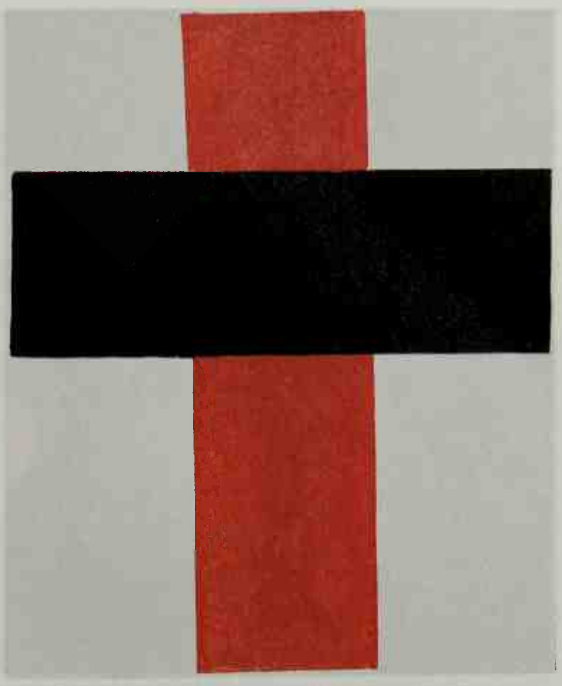
De Stijl (*The Style*) developed in the Netherlands at the same time as Russian nonobjective art and worked toward the same conclusions. Like the Russian artists, artists in De Stijl tried to produce a legitimate response to the chaos of World War I. The primary spokesperson for the movement was Piet Mondrian. Like many artists of his time, he spent several years in Paris absorbing the lessons of cubism. Mondrian returned to the Netherlands briefly during the war. There he met fellow painters Theo van Doesburg and Bart van der Leck, with whom he formed De Stijl. Architect J. J. P. Oud and designer Gerrit Rietveld joined later.

De Stijl sought the collaboration of artists in the related fields of painting, sculpture, architecture, and industrial and graphic design. The movement emphasized the need for "abstraction and simplification." Almost immediately, De Stijl painters began exhibiting simplified compositions in the form of rectangles and straight lines. They restricted their palette to the primary colors of red, blue, and yellow.

Under the influence of De Stijl, Mondrian's painting was transformed from the cubism he had practiced in Paris into a style much tighter and more geometric. In *Composition* (this page), he typically limited his palette to a few bright colors plus black and white. His forms consist of squares, rectangles, and horizontal or vertical bands of black. With such works, Mondrian made the artistic statement that paintings were no longer "windows" to another world. Instead, they were physical objects subject to the same design principles as a house or a chair.

In *Composition,* Mondrian removed the depth-producing devices that even the cubists used, such as shading, modeling, and perspective. In this painting, Mondrian was no longer concerned with producing the illusion of depth. His composition forces the eye to move from side to side, from the center of the canvas to the edge.

Dadaism. In the years following World War I, many artists saw even cubism as too tame and too rational for a world left in turmoil by the war's destruction. The movement called *dada* was born in Zurich, Switzerland, though it later flourished in New York City and Paris. The dada movement was an expression of irrationality directed at a world the dadaists believed had lost all reason and concern for human values. Yet, through its self-imposed irrationality, dada opened a new world of creative impulse. It developed guidelines that would encourage the use of chance occurrences and the conscious mind in creating art. Early members of the group included Jean Arp and Marcel Janco.



Dada originated in 1916 in the Cabaret Voltaire in Zurich. The members of the group selected the word randomly from a French dictionary. Early in its history, dada was primarily a literary movement in which poetry was created from a random selection of words. To create a dada work of art, Arp used a similar technique. He placed torn pieces of paper into a box, and after

shaking the box, he allowed the scraps to spill out onto a sheet of paper. He then pasted the pieces down according to the pattern in which they fell. He allowed randomness and chance to dictate the final composition of the picture.

Arp's German colleague Kurt Schwitters also adopted an unconventional approach to making art. Schwitters's work developed out of the synthetic cubism style, but he was even more aggressive in incorporating everyday objects into his works. Schwitters's *Merz Drawing* appears in the **Collage** article. Schwitters incorporated actual trash, including a button and a used envelope, in this composition. By using identifiable rubbish, Schwitters raised questions about the difference between art and nonart.

Surrealism. The artists who became the surrealists gathered around poet André Breton in Paris in the 1920's. The first Surrealist Manifesto was published in 1924, declaring the artistic goals of the organization, especially as conceived by Breton. For Breton, surrealism was a creative method that employed many of the ideas of Sigmund Freud, the Austrian physician who developed psychoanalysis as a method of treating mental illness. The basic strategy for Breton was *automatism,* a process for tapping the unconscious by writing in a trancelike state and recording the involuntary images that emerged. Taking his cue from the writings of Freud, Breton believed that dreams were the natural expression of the unconscious mind. Automatism, irrational thought associations, hallucinations, and the recollection of dream images offered a way to liberate the creative mind from the bonds of logic and reason.

Surrealism, like dada, began primarily as a literary movement. However, artists did organize themselves under the name of surrealism and staged a series of exhibitions. Gradually, the artists moved away from the influence of Breton and developed a broader appeal to artists and viewers alike.

Two branches of surrealist painting developed in Paris in the mid-1920's. *Abstract surrealism* included the work of André Masson of France and Joan Miró of Spain. *Illusionistic surrealism* included the work of Salvador Dali of Spain, Max Ernst of Germany, Yves Tanguy of France, and Paul Delvaux and René Magritte of Belgium.

The most important of the abstract surrealists was Joan Miró. He was born in the Catalonia region of Spain but moved to Paris in 1919. He resisted joining the surrealism movement officially, but even his earliest works exhibit a closeness to the surrealist style. Miró's paintings typically combine folk tales, humor, and absurdity. In *Carnival of Harlequin* (page 81), he developed an art of both abstraction and fantasy in a painting populated by strange and fantastic shapes that suggest living forms. Miró claimed that he generated his forms without preparation or planning, allowing his mind and his hand to wander playfully across the surface of the picture.

The work of the illusionistic surrealists contains highly realistic representations of dream states or hallucinations. Salvador Dali's *The Persistence of Memory* (page 84) is an example of what the artist called "hand-painted dream photographs." Works like these brought a new level of realism to painting. The illusionistic surrealists believed that realism, if pressed to extreme detail, could undercut the viewer's sense of reality, resulting in something almost ridiculous. There is a theatrical flavor to these works, particularly in Dali's paintings, where watches droop and a jellyfish walks on the land. The illusionistic surrealists hoped that by demonstrating the absurdity they saw in worldly existence they could awaken others to the irrational within themselves.

With the outbreak of World War II in 1939, many surrealist artists immigrated to New York City. This influx of European artists to the United States proved to be an enormous inspiration to young American artists, who suddenly found themselves in the company of great European masters. For other examples of surrealism, see **Dali, Salvador; Miró, Joan; Surrealism.**

The 1900's in North America

The new approaches to painting that developed in Europe did not make a great impact in the United States during the first years of the 1900's. Continuing a tradition developed after the end of the American Civil War in 1865, ambitious American artists went to Europe for advanced academic training. Lacking a strong artistic tradition in the United States, these artists relied upon Europe for inspiration as well as education.

Stieglitz and "291." The individual most responsible for bringing new styles of painting to the United States was photographer Alfred Stieglitz. He became the leader of the *Photo-Secession* movement, which championed photography as an art form. In furthering the movement's aims, he opened a gallery in New York City. It was located at 291 Fifth Avenue and was commonly called "291."

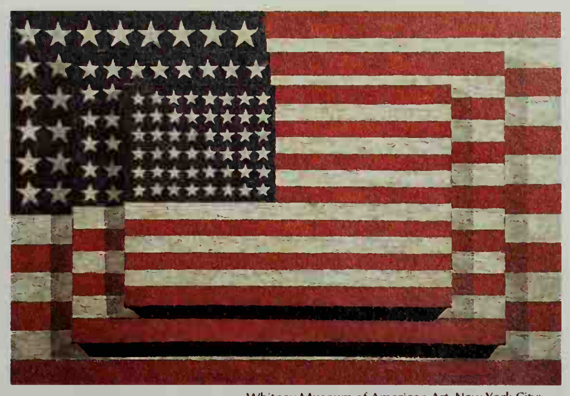
Stieglitz exhibited more than photographs at "291." The gallery became the first in the United States to exhibit paintings by such European masters as Cézanne, Matisse, and Picasso. Gradually, Stieglitz became less interested in European art and more concerned with establishing a new art movement on American soil. He provided an exhibition space for several young American artists. He supported these artists not only by exhibiting and selling their work, but also by providing encouragement, reviews, and publicity. The artists Stieglitz exhibited at "291" included such important American painters as Charles Demuth, Arthur Dove, Marsden Hartley, and Georgia O'Keeffe.

Precisionism was the first new style of the 1900's to emerge in the United States. It originated in the 1920's with Charles Demuth and Charles Sheeler as its leaders.

Precisionism merged with cubism and realism into a distinctly American style. Precisionism eliminated the complexities of analytic cubism but made something more abstract and angular of its realistic themes. The subject matter of precisionist painting consisted largely of views of the buildings and industrial structures typical of the American landscape. For example, Demuth's *My Egypt* (page 82) portrays a grain elevator in Lancaster, Pennsylvania.

Georgia O'Keeffe came to represent the new American approach to art. O'Keeffe, who was married to Alfred Stieglitz, spent her career painting particularly American subjects in realistic detail. She created dozens of abstract paintings, but she is perhaps best known for her carefully observed paintings of simple objects, such as shells, rocks, and flowers. In such works as *Black Iris* (page 82), O'Keeffe combined precise observation with a keen sense of design.

Regionalism. Stieglitz and such artists as Demuth and O'Keeffe were important because they forged a unique American identity out of European art of the 1900's. But some American artists rejected the art principles of Europe in favor of a vision of homespun Americanism. In the late 1920's, many American artists became strongly anti-European. They developed an approach to painting called *regionalism.*

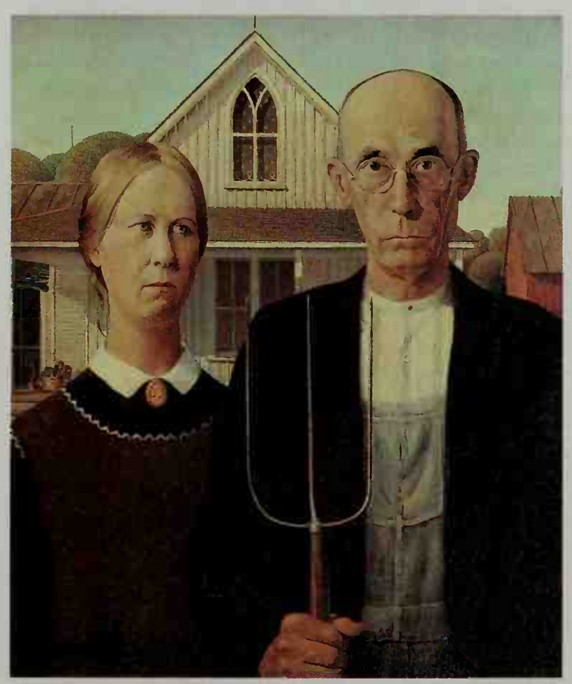


Regionalism was a movement that sought to glorify traditional American values in art, especially those of the rural Midwest. The movement insisted above all on the rejection of European ideas. Key artists in the regional movement included Thomas Hart Benton; Grant Wood; and John Steuart Curry.

During the 1930's, Benton attempted to move the center of the American art world away from New York City to the heartland of the country, the Midwest. Benton and other regionalists cultivated a nostalgic interest in the local scenes of American life that were disappearing. As the spokesperson for regionalism, Benton attacked European art and the international character of New York-based artists, especially those associated with Alfred Stieglitz.

To counteract European art, Benton developed a monumental style that found its expression in many large murals in public buildings. Benton's mature style can be seen in murals he painted for the State Capitol in Jefferson City, Missouri, in 1936. An example appears in **Western frontier life in America** (Law and order). In such works, Benton referred to Renaissance painting for stylistic influences. His figures, with their bulging, muscular bodies, resemble those seen in the paintings by Michelangelo.

Grant Wood received art training in Paris during the early 1920's. On a trip to Germany in 1928, he discovered the works of Flemish and German artists of the 1400's that inspired him to return to realism. Wood was soon producing paintings that combined ease of understanding with an unassuming charm. Wood's *American Gothic* (this page) is perhaps the most famous of all regionalist paintings. It transcends the seriousness of most regionalist art in favor of a delicate humor. The humor comes from Wood's placement of a typical American farmer and his daughter with European Gothic-style windows in the background.



Like Benton and Wood, Curry gained recognition for painting scenes of Midwestern life, such as a religious baptism and a farm family fleeing an approaching tornado. For an example of his work, see the article **Curry, John Steuart.**

Modern Mexican painting. There were two major challenges to the regionalist hold on American painting during the 1930's and 1940's. The first came from the arrival of mural painters from Mexico.

The Mexican muralists were Diego Rivera, José Orozco, and David Siqueiros. Rivera, perhaps the best known of the three, received several major mural commissions in the United States during the 1930's. His most significant commission was the *Detroit Industry* murals executed at the Detroit Institute of Arts.

Rivera worked toward creating a national Mexican style that reflected the history of the Mexican people as well as the socialist spirit of the Mexican Revolution of the early 1900's. Rivera's mural style influenced artists in both Mexico and the United States. It combined decorative folklore elements of the Mexican art tradition with dramatic realism.

Another influential Mexican painter of the 1930's was Frida Kahlo, who was married to Diego Rivera. Kahlo's paintings were largely autobiographical in subject matter. She produced many self-portraits depicting herself in different psychological states. Stylistically, she was interested in the kinds of heroic representation produced by her husband. However, more than Rivera, she was firmly rooted in the traditions of Mexico and almost always portrayed herself in traditional Mexican costumes. Her subject matter is also concerned with traditional Mexican culture. In *Self-Portrait with Thorn Necklace and Hummingbird* (this page), Kahlo wears a thorn necklace that draws blood from her neck, referring to the ritual bloodletting practiced by Aztec priests in ancient Mexico. For other examples of Mexican painting, see **Aztec; Indian, American** (introduction); **Latin America** (The arts); **Mexico** (Arts); **Orozco, José Clemente; Rivera, Diego.**

Europeans in America. The second major challenge to regionalism came from the arrival of many leading European artists who settled as refugees in the United States during World War II. One such artist was Piet Mondrian, who arrived in New York City in 1940 and died there in 1944. Most of the important surrealists also came to the United States. They included André Breton, Max Ernst, Yves Tanguy, and André Masson, as well as Marcel Duchamp, who was close to both the surrealists and dadaists.

With the presence of many European painters, as well as Mexican muralists, New York City became a painting center unsurpassed anywhere in the world. The presence of so many important artists provided a framework for the formation of a new American style. The Europeans were a powerful influence on the first important American art movement of the postwar period, abstract expressionism.

Abstract expressionism was a loosely organized movement. The pictures of the abstract expressionists

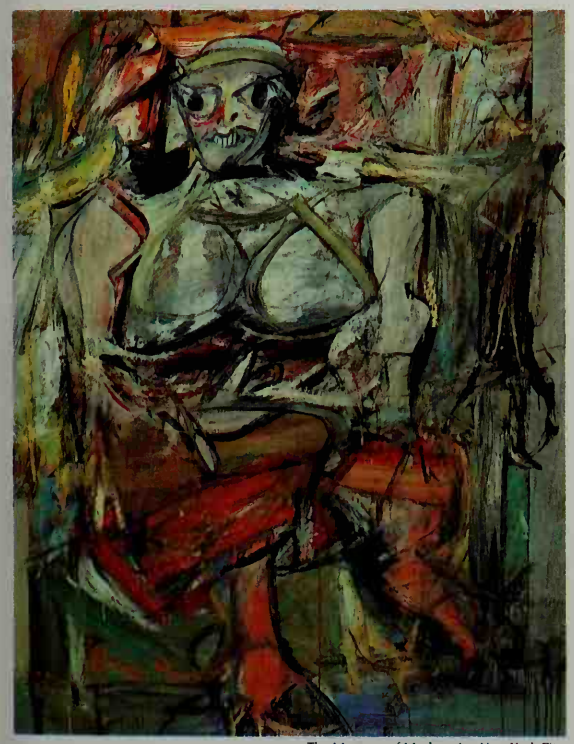
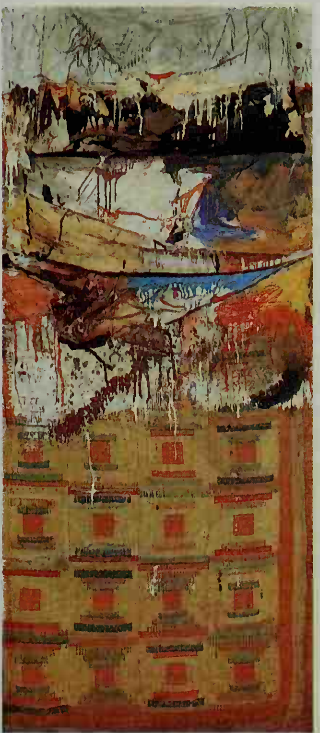
did not resemble one another's in most cases, but they all shared a desire to create an important American tradition of painting. Although the abstract expressionists developed diverse styles, they still worked to make something genuinely expressive from the abstract tradition they inherited from Europe.



One of the first artists to develop in the 1940's was the Dutch-born Willem de Kooning. Although most of his colleagues painted in a totally abstract style, de Kooning was one of the most persistent in maintaining the human figure in his work. He began to exhibit a series of paintings that depict full-bodied, wide-eyed, toothy women who loom in large, abstract space. The most famous of this series is *Woman, I* (this page). De Kooning constructed the pictures in layers of thick paint, applied with an urgent, even violent feeling. Many viewers were offended by the images of the women, while others were moved by their vitality. By the mid-1950's, de Kooning was painting totally abstract pictures full of lush, thick paint. An example, *Easter Monday,* appears in the article **De Kooning, Willem**.

Perhaps the most renowned of the abstract expressionist painters was Jackson Pollock. Pollock radically altered the traditional techniques of painting when he poured his paint onto canvases that were tacked to the floor. The results were compositions made up of tangles of poured paint. The lines formed by the fluid reflected the movements of the artist's arm as he dripped the paint onto the canvas. Pollock produced several mural-sized canvases filled with dense, dripping lines that became a kind of automatic writing related to the technique that was practiced by the surrealists. The character of each of Pollock's "drip" paintings differs in their patterns, rhythms, densities, and textures. An example of a Pollock painting appears in **United States** (The arts).

In general, the early abstract expressionists favored untraditional materials applied in new ways. For example, both Pollock and de Kooning used car enamels and house paints when they wanted their paintings to have an especially raw look.



The quickness and energy of de Kooning's brushstrokes and Pollock's drip paintings are evident in the finished works, leading to the term *action painting* to describe the painting process. Another group of abstract expressionists emerged later than the action painters. They were called *field painters* and included Barnett Newman, Mark Rothko, and Clyfford Still.

Newman painted large canvases that often consist of one strong color, sometimes divided by horizontal or vertical stripes. Rothko eliminated subject matter in his paintings around 1947 and adopted washes of color that seem to drift across the canvas. For Rothko, color takes over for the gestures of Pollock and de Kooning in works like *Number 8,* which appears in the article **Rothko, Mark**. Rothko meant his paintings to be perceived at once, as a whole. Similar concerns can be seen in Clyfford Still's work. Still's expanses of color are less transparent than Rothko's. Instead, Still constructed his paintings from thickly applied paint. The compositions evoke images of prehistoric landscapes. Areas of color

Color-field painting. A group of artists emerged during the 1950's and 1960's who moved away from both subject matter and the outward emotionalism found in abstract expressionism. They tried to reduce painting to the purity of color on a flat plane. These artists became known as *color-field painters* and included Helen Frankenthaler, Morris Louis, Kenneth Noland, and Jules Olitski.

The color-field painters abandoned the brush marks that had been so vital to many abstract expressionists. Instead, they introduced a technique in which thinned paint was poured onto unprimed canvas and allowed to soak into the canvas in abstract designs. Helen Frankenthaler was the first artist to use this technique effectively in her landmark painting *Mountains and Sea* (page 29). Frankenthaler was influenced by the poured paintings of Jackson Pollock. She attempted to work automatically as Pollock had done, capitalizing on accidents and spills to create the painting's composition.

Morris Louis and Kenneth Noland saw *Mountains and Sea* almost immediately after its completion and began experimenting with the same technique. They were soon producing mural-sized paintings filled with translucent color. Their works eliminated subject matter and drawing in favor of pure color.

The revival of subject matter. During the postwar period, some artists tried to restore subject matter to painting. During the mid-1950's, Robert Rauschenberg and Jasper Johns believed that art could be changed through addition rather than reduction. To this end, they adopted the collage technique, adding paper, cloth, and other objects to the surface of their canvases. Gradually, the work became more sculptural. Objects as diverse as stuffed birds and inflated tires became part of their art. Both Rauschenberg and Johns looked to the work of dada artists, such as Kurt Schwitters, as a model for creating their work.

In Rauschenberg's *Bed* (page 85), the artist combined sheets, a pillow, and a quilt as the components of his construction. He forced the cloth elements to function as a kind of canvas as he smeared the surface with paint. This type of construction has been called an *assemblage,* referring to the act of gathering materials and combining them to build images. See **Rauschenberg, Robert** (picture).

Jasper Johns produced assemblages, but he is perhaps best known for his paintings of flags, targets, and numbers. In *Three Flags* (page 83), Johns precisely painted a version of the American flag. He executed *Three Flags* through the difficult medium of encaustic, in which the colors are mixed with wax and heated. Johns attached no meaning to his flag, claiming that it was the most basic design he could find to paint. Like Rauschenberg, however, Johns was searching for a new content for painting, one that could not be accused of sentimentality or storytelling.

Pop art. The work of Rauschenberg and Johns became enormously important in the development of pop art during the 1960's. Pop art took its themes from subjects not previously associated with fine art. These subjects included comic strips, motion pictures, and especially advertising and other types of commercial art. The chief pop artists were Jim Dine, Roy Lichtenstein, James Rosenquist, and Andy Warhol.

Pop art challenged the fine arts tradition in more than just its subject matter. Pop artists used many of the techniques of commercial artists to achieve new effects. For example, in many of his paintings, Lichtenstein used tiny *benday* dots of color he created with a perforated metal screen and a toothbrush. Benday dots make up the images in color comics. The dots are used in the right half of Lichtenstein's *Whaam!* (this page).

Many viewers considered pop art to be playful and trivial. However, pop artists were serious about their work. They rejected the sense of superiority they saw in postwar abstraction and favored an art that would appeal to a broader segment of society.

Andy Warhol exploited commercial silk-screen techniques, making paintings by forcing ink or paint through a piece of silk onto canvas. The silk-screen process allowed Warhol to use any available printed image as a source for his painting. Additionally, with the silk-screen, Warhol could reproduce his images over and over in virtually identical copies. In the *Marilyn Monroe Diptych,* which appears in the article **Warhol, Andy,** he used the same screen to repeat the movie star's image across the length of the canvas. He could also use the same screen to reproduce additional canvases. Many of Warhol's works were multiple images of newspaper photos, soup cans, and automobile accidents. For other examples of pop art, see **Oldenburg, Claes; Pop art.**

Minimal art was an abstract style that appeared particularly in the United States during the 1960's. Minimal painters such as Agnes Martin and Frank Stella concentrated on color, line, and shape. Most minimal works have a unified composition and emphasize geometric abstraction. An example appears in the article **Stella, Frank.**

New image painting. In 1978, the Whitney Museum of American Art in New York City presented a group of artists in an exhibition called "New Image Painting." The new imagists included Jennifer Bartlett, Neil Jenney, and Susan Rothenberg. The group shared a revived interest in *figurative painting,* which depicts human figures and other recognizable subjects. They believed in the potential of painting that was more openly communicative than the styles that had preceded them.

Susan Rothenberg painted canvases that combined an interest in figurative subject matter with an interest in the more formal properties of design. In the mid-1970's, the flat silhouette of a horse appeared in her paintings. Eventually, the horse yielded to the human figure in her work. In her later paintings, Rothenberg's figures float in a submarine world of fluid brushwork, the figures silhouetted against shimmering luminous paint. An example of this phase of her work is *Mondrian Dancing* (page 88).

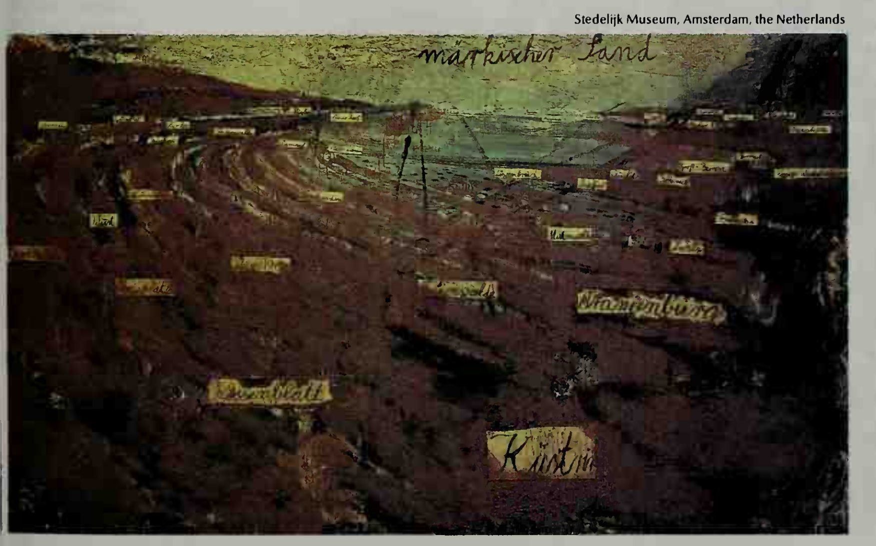
Recent painting



The new image painters set the stage for explosive developments in painting during the 1980's. Much of the important new painting developed in Europe.

Neoexpressionism. German artists were in the lead in reviving the technique of painting. The works of Anselm Kiefer and Georg Baselitz showed a new tendency toward expressionism. By 1980, their paintings were referred to as *neoexpressionism.* The term since has been broadened to include works by American, British, and Italian artists.

Neoexpressionism in Germany showed the influence of The Bridge and The Blue Rider expressionist styles of the early 1900's. The neoexpressionists were also influenced by abstract expressionism. The best known of the German painters is Kiefer. He has produced paintings in which he explores memories of Nazi Germany and of the Holocaust, the mass murder of European Jews by the Nazis. Kiefer also went back into art history, incorporating elements of the art of Caspar David Friedrich, French sculptor Auguste Rodin, and Vincent van Gogh. Kiefer almost single-handedly revived an interest in German romantic painting, creating works on a large physical scale.

Kiefer painted several symbolic landscapes, such as *Märkischer Sand* (*March Sand*), shown on this page. In this work, Kiefer presents a vast panoramic field with furrowed lines sweeping majestically toward the horizon. The field is labeled with the names of German towns. As if to emphasize the unchanging character of

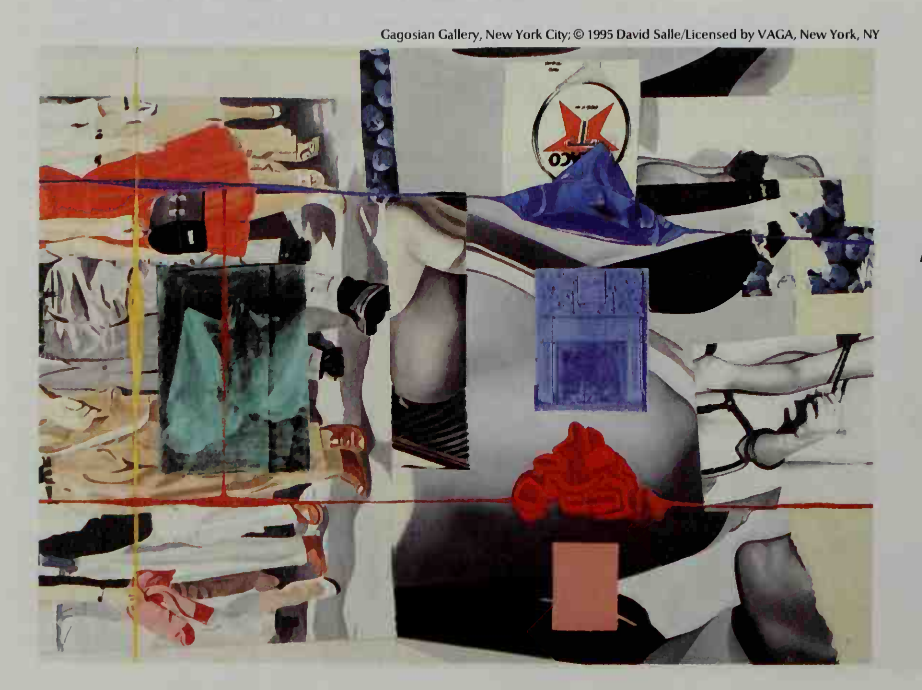
the land, Kiefer mixed sand into the paint. He also added sand in other landscapes, as well as grass, straw, and twigs.

Baselitz paints upside-down figures that symbolically represent two sides of Germany, a country politically divided until 1990. More than Kiefer, Baselitz regards himself as an abstract painter. He believes that by turning his figures upside down, he has discharged them of their traditional subject matter, allowing the viewer to focus on the painterly brushwork.

Another German artist, Gerhard Richter, has worked in a broad variety of styles including neoexpressionism. Some of his paintings are richly colored abstractions, but he has also worked in a figurative style. Some of Richter's works combine painting with photography.



American versions of neoexpressionism have been far less political than the German variety. Such artists as Julian Schnabel and Jean-Michel Basquiat produced canvases that featured prominent brushwork meant to visually lure the viewer into the picture. Schnabel's work from the early 1980's emphasizes broken crockery that has been glued to the surface of the painting. These pieces of broken plates act as an extension of the brushstrokes, adding shape, color, and texture to the painting.

Basquiat's career straddled neoexpressionism and the *graffiti* movement. Graffiti artists, led by American artist Keith Haring, painted or scratched words or drawings on the walls of public places. Basquiat was born into a Haitian-Puerto Rican family, and the subject matter of his paintings reflects his cultural background. Basquiat began executing graffiti art on the street. Gradually, he began to work on canvases in which he combined many verbal signs—names, titles, phrases, and poetry—with an odd assortment of forms. These forms included masks and skulls, as well as cartoonlike figures that resembled robots. An example is his *Hollywood Africans* (page 87). Basquiat died at the age of 28, just as he was establishing himself as a mature artist.

Post-modernism. The theories of post-modernism had an impact on painting of the late 1900's. Post-modernism has so many meanings that a single definition is impossible. In general, post-modern art values communication as a primary goal, but it insists that understanding works of art is never clear or easy. Several painters explored post-modern ideas in their works, including the American artists Eric Fischl, Sherrie Levine, Robert Longo, and David Salle.

Fischl painted figurative works, many with disturbing sexual overtones. Longo paints modern urban themes. Levine gained prominence for her graphite and watercolor reproductions of the works of such modern masters as Kasimir Malevich and Piet Mondrian.

Salle's work uses different elements, both words and images, and combines them in surprising ways, as in *Picture Builder* (page 88). Salle allows his images to overlap, forcing the viewer to search for possible meanings and connections among the painting's visual elements.

Salle's art demonstrates the post-modern belief that any form of representation is valid. This belief allows the artist to comb through all the visual material in his or her world, increasing the potential for art to describe every possible experience. Paisley, *PAYZ lee,* is a town in western Scotland about 7 miles (11 kilometers) west of Glasgow. For location, see **Scotland** (political map). Paisley is the largest town in the Renfrew District, which has a population of 203,447. The town is known for the patterned shawls it produced during the 1800's. *Paisley* is also the name of the design that imitates the pattern used on these shawls. A. S. Mather

Paisley, Ian (1926-), is a Protestant minister and a political leader in Northern Ireland. He became known for his strong support of Northern Ireland's continued union with the United Kingdom.

Ian Richard Kyle Paisley was born in Armagh, Northern Ireland. He studied at Reformed Presbyterian Theological College in Belfast and was ordained a minister in 1946. Paisley founded the Free Presbyterian Church of Ulster in Belfast in 1951. He was elected to the British House of Commons in 1970. In 1971, he helped found the Democratic Unionist Party, which opposes the sharing of power with Roman Catholics in Northern Ireland. He became a member of the European Parliament in 1979.

Paisley was once imprisoned for urging followers to block a Catholic civil rights demonstration. He was ejected several times from the House of Commons and the European Parliament for his fiery outbursts. Paisley opposed the 1998 peace agreement that established a power-sharing legislative assembly for Northern Ireland. He was elected to the assembly in 1998 and vowed to block full implementation of the agreement.

Paiute Indians, *py YOOT,* is the name of two tribal groups of the western United States—the Northern Paiute and the Southern Paiute. About 8,000 Northern Paiute and about 1,800 Southern Paiute live on reservations, in federal colonies, and in many communities of Arizona, California, Nevada, Oregon, and Utah. The people work in agriculture, crafts, tourism, and various urban industries.

The Northern Paiute once lived in the area extending from Owens Lake in California, through Nevada, to just south of the Columbia River in Oregon. The Southern Paiute ranged from the Mojave Desert of California to the Colorado River in Arizona, and then north to central Utah. Small groups of Paiute moved about, hunting antelope, deer, mountain sheep, rabbits, and other game. These groups of Paiute also collected berries, nuts, roots, and seeds. The Northern Paiute who lived around the lakes and marshes of western Nevada earned their livelihood by fishing. Some Southern Paiute planted beans, corn, and squash.

The Paiute lived in cone-shaped houses made of brush. They wove baskets from grass, reeds, and willows. The Paiute religion centered around spirits of nature.

During the 1800's, the Northern Paiute fought white settlers who had come into the region. The Indians won an important victory at Pyramid Lake in Nevada in 1860. The Southern Paiute remained peaceful, though they were raided occasionally by the Ute and Navajo Indians, who sold them as slaves on the Mexican frontier. In the 1860's and the 1870's, the U.S. government established reservations for both groups of Paiute.

Pakistan

Pakistan is a Muslim country in southern Asia officially called the Islamic Republic of Pakistan. Its capital is Islamabad, and its largest city is Karachi.

Almost all the people of Pakistan practice Islam, the Muslim religion. Despite their common religion, Pakistanis have strong ties to different cultures. The major cultural groups include Punjabis, Sindhis, Pashtuns (or Pakhtuns), and Baluchi. Each group speaks a different language and inhabits a different part of the country. Urdu is the official language of Pakistan, but less than 10 percent of the people speak it as their primary language. Pakistan has struggled to bring the different cultures together into a unified nation.

Pakistan's natural features are as diverse as its cultural groups—towering mountain ranges, high plateaus, lush green plains, and arid deserts. Most of the people live in the irrigated plains of eastern Pakistan. The most densely populated part is the Punjab, a rich agricultural region in the northeast. The western part of the country is sparsely populated because of its dry climate and its barren, rugged, mountainous terrain.

The majority of Pakistan's people live in rural areas, though Pakistan's cities are growing rapidly. Most of Pakistan's rural inhabitants work in agriculture and follow traditional clan and tribal customs. By contrast, people in the urban areas engage in a range of professions, and many have adopted modern ideas and values. Although Pakistan has made rapid strides in industrialization, its economy still relies heavily on agriculture.

Pakistan's history dates back thousands of years. About 2500 B.C., a sophisticated civilization emerged in the Indus Valley, centered around the cities of Mohenjo-Daro and Harappa. Later, over the course of several thousand years, a variety of peoples—Afghans, Arabs, Greeks, Persians, and Turks—came to the region.

In the 1800's, the area that makes up Pakistan and India came under British colonial rule. In 1947, Pakistan was created as a homeland for Muslims, while India was primarily Hindu. The people of Kashmir were Muslim, but the region was ruled by a Hindu prince who tried to join his lands to India. Pakistan and India have struggled over control of the region ever since.

Pakistan initially consisted of two parts called East Pakistan and West Pakistan. More than 1,000 miles (1,600 kilometers) of Indian territory separated the two sections, but the people in both sections were Muslim. West Pakistan tended to dominate East Pakistan, which had a majority of the population. In 1971, East Pakistan won a nine-month civil war and became the independent nation of Bangladesh (see **Bangladesh**).

Government

In 1999, General Pervez Musharraf led a military coup that overthrew Pakistan's democratically elected government. He dissolved the parliament, suspended the Constitution, and declared himself head of a transitional government. Pakistan's Supreme Court ordered that civilian government be restored by October 2002, and

Ayesha Jalal, the contributor of this article, is Professor of History at Tufts University and coauthor of Modern South Asia: History, Culture, Political Economy.

Musharraf agreed. In 2001, Musharraf elevated himself to the presidency, and in 2002, he enacted sweeping changes to the Constitution that cemented his hold on power. Before the coup, Pakistan had a parliamentary system of government.

National government. Before the 1999 coup, an elected prime minister headed the Pakistani government, and the president served as the head of state. The Cabinet and the prime minister were members of a two-chambered parliament. The prime minister was the leader of the party with the most seats. In the upper house, called the Senate, the four provinces of Pakistan had equal representation. Provincial assemblies, elected by the voters, chose the members of the Senate. The people directly elected the members of the lower house, called the National Assembly.

Provincial and local government. Pakistan has four provinces—Baluchistan, North-West Frontier Province, the Punjab, and Sind. Before the military take-over, each province had an elected assembly. Elected and appointed officials govern cities, towns, and villages.

The federal government rules Pakistan's capital, Islamabad, as a separate district called the Capital Territory of Islamabad. Areas called Federally Administered Tribal Territories lie in northwestern Pakistan.

Politics. The Pakistan Muslim League (PML) and the Pakistan People's Party (PPP) are the two largest political parties in Pakistan. The PML's main support base is in the Punjab, while the PPP has a strong following in Sind as well as in parts of the Punjab and the North-West Frontier Province. Other parties include religious parties, such as the Muslim parties Jamaat-i-Islami and the Jamiat-i-Ulama-Islam. Beginning with local elections in 2000, the voting age was reduced from 21 to 18.

Courts. The Supreme Court is Pakistan's highest court. Its decisions are binding on all Pakistani courts, including the Federal Shariat Court, which oversees Islamic aspects of law. Each province has a High Court and other courts with civil and criminal jurisdiction.

Armed forces. An army of more than 500,000 and a smaller navy and air force are the main branches of the armed forces. Military service is voluntary, and the minimum age to volunteer is 17.

Karachi is Pakistan's largest city and commercial center. It is also the country's chief port and the capital of Sind Province. Karachi lies in southern Pakistan on the coast of the Arabian Sea.

People

Ancestry. Pakistan's people are descended from many different cultures. The earliest inhabitants in the region belonged to the same ethnic group as the people in northern India. Over the centuries, Afghans, Arabs, Greeks, Persians, and Turks came with invading armies. Many of the invaders settled in the area and intermarried with the inhabitants. These multiple influences added layers of variety to Pakistani culture.

Cultural groups and languages. Despite the bond of Islam, cultural differences divide the people of Pakistan. Each group has its own language and customs. Some Pakistanis feel greater loyalty to their own cultural group than to the nation.

Language is an important factor that distinguishes cultural groups. Major regional languages include Baluchi, Punjabi, Pashto (also called Pakhto), and Sindhi. Urdu is Pakistan's official language, but less than 10 percent of the people speak it as their primary language.

The Punjabis, the largest cultural group, speak different dialects of the Punjabi language. They live mainly in the Punjab but have a presence in other parts of the country, especially Karachi. Members of this group control the government, economy, and armed forces.

Urdu-speaking Muhajirs immigrated to Pakistan from India when the two countries separated in 1947. The Muhajirs became prominent in government after independence, but they have since lost power. Their descendants, most of whom live in Karachi or Hyderabad, blame Punjabi dominance for their declining influence.

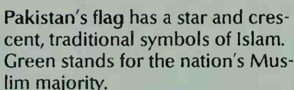
Other leading groups include the Sindhis, the Pashtuns (also called Pakhtuns), and the Baluchi. The Sindhis have a slight majority in Sind but are outnumbered by Muhajirs and other non-Sindhi groups in major cities, such as Karachi. Muhajirs and Sindhis have clashed over educational and employment opportunities and political control of Karachi. The Pashtuns, who belong to various tribes and speak Pashto (or Pakhto), inhabit the North-West Frontier Province and the northern part of Baluchistan. Baluchis consist of several nomadic and tribal groups. They speak dialects of Baluchi and live in Baluchistan, the largest but least populated province of Pakistan. Baluchistan is also home to smaller cultural groups, such as the Brahuis, Makranis, and Lassis.

Millions of refugees from Afghanistan form another cultural group in Pakistan. They fled to Pakistan to escape decades of war in Afghanistan. They live mainly in the North-West Frontier Province and Baluchistan but also have a sizable presence in Karachi.

Way of life

Rural life. About two-thirds of Pakistanis live in rural areas. Most of them are farmers, herders, and skilled workers, such as carpenters and bricklayers. Local customs and beliefs play an important part in rural life.

Housing and clothing vary from one region to another, depending on climate, local customs, and economic conditions. Most rural villages consist of clusters of two- or three-room houses made of clay or sun-dried mud.



Pakistan in brief

General information

Capital: Islamabad.
Official name: The Islamic Republic of Pakistan.
Official language: Urdu.
Largest cities (1981 census):

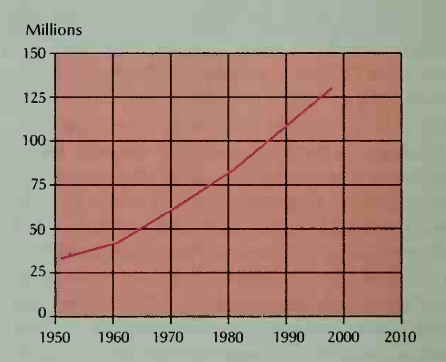
Karachi (5,208,170)	Faisalabad (1,104,209)
Lahore (2,952,689)	Rawalpindi (794,843)

Pakistan's flag has a star and crescent, traditional symbols of Islam. Green stands for the nation's Muslim majority.

A wreath of narcissus, the national flower, encircles a shield on the Pakistani coat of arms.

Land and climate

Land: Pakistan lies in southern Asia, north of the Arabian Sea. It borders Iran, Afghanistan, China, and India. Mountains cover most of northern and western Pakistan. The Thar Desert covers much of southeastern Pakistan, and most of southwestern Pakistan is an arid plateau. A major river system waters the fertile plains of central Pakistan.
Area: 307,374 mi^2 (796,095 km^2). *Greatest distances*—north-south, 935 mi (1,505 km); east-west, 800 mi (1,287 km). *Coastline*—506 mi (814 km).
Elevation: *Highest*—K2 (in Kashmir), 28,250 ft (8,611 m) above sea level. *Lowest*—sea level.
Climate: Most of Pakistan has a dry climate, with hot summers and cool winters. Pakistan averages only about 10 inches (25 centimeters) of rain a year. But the amount of rainfall varies greatly from year to year. Long dry spells may be broken by severe rainstorms that cause rivers to overflow and flood the countryside.



Government

Form of government: Federal republic.
Head of state: President.
Head of government: Prime minister.
Legislature: Parliament of two houses—the National Assembly and the Senate.
Executive: Prime minister and president each have some executive powers.
Judiciary: Highest court is the Supreme Court.
Political subdivisions: Four provinces and the Capital Territory of Islamabad.

People

Population: *Estimated 2002 population*—144,135,000; *1998 census*—130,579,571.
Population density: 469 per mi^2 (181 per km^2).
Distribution: 67 percent rural, 33 percent urban.
Major ethnic groups: Punjabi, Sindhi, Pashtun (or Pakhtun), Baluchi, and Muhajir.
Major religions: 77 percent Sunni Muslim, 20 percent Shiite Muslim, 3 percent other, including Christian and Hindu.

Population trend

Year	Population
1951	33,779,500
1961	42,880,000
1972	64,892,000
1981	84,253,000
1998	130,579,571

Economy

Chief products: *Agriculture*—wheat, cotton, rice, sugar cane, milk, chickpeas. *Manufacturing*—cotton textiles and clothing, food products, fertilizer, steel, cement. *Mining*—natural gas, petroleum.
Money: *Basic unit*—Pakistani rupee. One hundred paisas equal one rupee.
Foreign trade: *Major exports*—textiles, including garments, cotton cloth, and yarn; agricultural products; leather goods; and carpets. *Major imports*—petroleum goods, machinery, transportation equipment, and chemicals. *Major trading partners*—United States, United Kingdom, Japan, Germany, Saudi Arabia, United Arab Emirates.

Most of these homes have little furniture. People sit and eat on earthen floors covered by straw or woven mats. Many homes lack basic plumbing and electric power.

City life. A majority of urban dwellers cannot read or write, or can read and write only a little. Most earn a living as unskilled laborers, factory workers, shopkeepers, or craftworkers. Many live in modest houses in old, crowded neighborhoods or in makeshift homes on empty plots of land. Sanitation is poor in the inner cities.

The middle and upper classes, who make up a small percentage of the population, reside in spacious homes in comfortable urban neighborhoods. Many of these people have been educated in English and know a great deal about Western styles and ideas. They stand in stark contrast to the majority of Pakistanis, who are rooted in their traditional cultures.

Clothing. Pakistanis wear different clothing depending on their region. The most common garment worn by both men and women is the *shalwar-qamiz* (or *salwar-kameez),* which consists of loose trousers and a long, knee-length shirt. Women also wear a *dupatta* (scarf) or a shawl called a *chador* or *chadar* over the shoulders and head. Outside the home, some women cover themselves with a tentlike garment called a *burqa* or *burka.* In parts of the Punjab, some men wear skirtlike garments called *dhotis* or *lungis.* Many Punjabi women prefer the loose, skirtlike *ghagra* instead of the shalwar-qamiz. Turbans and woolen or fur caps are popular head coverings among Pakistani men.

Food and drink. Wheat and other grains are the staple diet of most Pakistanis. They eat flat loaves of bread called *chapattis* or *nans* with cooked lentils, vegetables, and mutton, beef, or chicken curries. *Biryani* and *pilau* are rice dishes mixed with meat, vegetables, raisins, and nuts. Pakistanis like food flavored with spicy seasonings. They do not eat pork, which is forbidden by Islam. Desserts such as *kheer* (a kind of rice pudding) and *halwa* or *halva* (a confection made with ground seeds or dried fruits or vegetables) are popular. Fresh and dried fruits are also eaten as desserts. Tea with milk and sugar is a favorite drink. In hot weather, Pakistanis enjoy a yogurt beverage called *lassi,* flavored with sugar or salt.

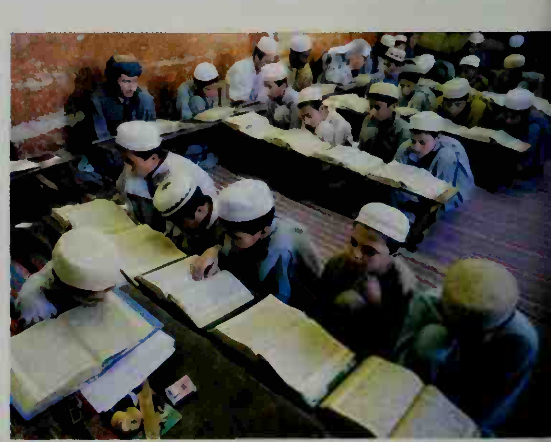
Recreation. Sightseeing, picnics, eating out, fairs, motion pictures, and theater are popular recreational activities in Pakistan. In rural areas, wrestling, horse racing, and *tent pegging* (a horse riding game) are favorite sports. Satellite television and movies on videotape have become popular, especially in urban areas. Interest has grown in organized sports, such as cricket, field hockey, football, tennis, squash, and volleyball.

Religion. More than 97 percent of Pakistan's people practice Islam. The majority of Pakistan's Muslims belong to the Sunni division of Islam. Only about 20 percent belong to the Shiite division. The end of Ramadan, the month of fasting, and the *hajj,* the annual pilgrimage to Mecca, are important religious holidays. People of other religions in Pakistan include Christians, Hindus, Buddhists, and Parsis.

Education. A little over half the men and less than a third of the women above the age of 15 can read and write. School attendance is not compulsory, and less than half of the children of school age attend school. Pakistan suffers from a shortage of schools, qualified teachers, and instructional materials. However, wealthy Pakistanis have access to high-quality private schools.

Islamic religious schools called *madrasahs* have become popular in both rural and urban areas. These schools teach the Qur'ān and other beliefs of Islam. Some of the schools foster religious extremism, although the government has tried to stop this.

Pakistan has over 20 universities and several private colleges. Some of the largest educational institutions are the universities of Karachi, Peshawar, and the Punjab.



The arts. Each region of Pakistan has its own folk literature, consisting of stories and songs about legendary or historical personalities. Folk theater based on myths and legends is immensely popular in the rural areas. In the cities, motion pictures—either in theaters or on video—are in great demand. Art and architecture in Pakistan show the influence of both Islamic and local cultural traditions. Pakistanis have a passion for folk, classical, and popular music, and several Pakistani musicians have acquired an international following.

Land and climate

Pakistan has five main land regions: (1) the Northern and Western Highlands, (2) the Punjab Plain, (3) the Sind Plain, (4) the Baluchistan Plateau, and (5) the Thar Desert.

Mountains cover much of northern and western Pakistan, known as the Northern and Western Highlands. K2, the second highest peak in the world, towers 28,250 feet (8,611 meters) above sea level in the part of Kashmir controlled by Pakistan. Only Mount Everest is higher. Mountain passes cut through the rugged peaks at several points. The most famous of these passes, the Khyber Pass, links Pakistan and Afghanistan. The mountain regions have the coolest weather. Summer temperatures in the north and northwest average about 75 °F (24 °C), and winter temperatures often fall below freezing.

The Punjab Plain and the Sind Plain occupy most of the eastern part of the country. These regions are *alluvial plains* (land formed of soil deposited by rivers). In the north, the Punjab is watered by the Indus River and four of its tributaries—the Chenab, Jhelum, Ravi, and Sutlej rivers. The combined waters of these four tributaries join the Indus River in east-central Pakistan. South

of this meeting point, the broadened Indus flows to the Arabian Sea through the Sind Plain.

In the Punjab, temperatures average over 90 °F (32 °C) in summer and about 55 °F (13 °C) in winter. The eastern part of the Punjab receives the most rain—more than 20 inches (51 centimeters) a year. Extensive irrigation systems have made the Punjab and Sind plains fertile agricultural regions.

The Baluchistan Plateau lies in southwestern Pakistan. Most of the plateau is dry and rocky and has little plant life. Much of the Baluchistan Plateau receives less than 5 inches (13 centimeters) of rain a year.

The Thar Desert lies in southeastern Pakistan and northwestern India. Much of the desert is a sandy wasteland. However, irrigation projects have made parts of the desert near the Indus River suitable for farming.

Most of Pakistan has a dry climate, with hot summers and cool winters. Pakistan averages only about 10 inches (25 centimeters) of rain a year. But the amount of rainfall varies greatly from year to year. Long dry spells may be broken by severe rainstorms that cause rivers to overflow and flood the countryside. In general, most of the rain falls from July to September, when the summer *monsoon* (seasonal wind) blows across Pakistan.

Economy

Pakistan has a developing economy. About a third of its people live below the poverty line. Agriculture remains the leading economic activity, but service industries and manufacturing have grown in importance.

The Khyber Pass is the easiest land route between Pakistan and Afghanistan. The pass cuts through the Safed Koh mountains, which are part of the Hindu Kush range. This part of the Khyber Pass is near Peshawar, Pakistan.

Natural resources. Pakistan's rivers are its most valuable natural resource. They supply water to irrigate over 38 million acres (15 million hectares) of farmland and also provide an important source of hydroelectric power. Central Pakistan has extensive natural gas reserves.

WORLD BOOK map

Agriculture employs about 40 percent of Pakistan's labor force and accounts for about 25 percent of its gross domestic product (GDP), the total amount of goods and services produced in the country. In the 1950's and again in the 1970's, Pakistan's government introduced land reforms to distribute land to the poor. It also tried to modernize agriculture by encouraging farmers to use fertilizers, pesticides, and new types of seeds. These efforts met with mixed success.

Wheat is the chief crop in Pakistan. Pakistani farmers also grow cotton, rice, sugar cane, chickpeas, oilseeds, fruits, and vegetables. Although mechanized agriculture has made some inroads, most farmers rely on cattle and water buffaloes to till the land. These animals also provide meat, milk, and hides. Many Pakistani farmers, especially in Baluchistan and the North-West Frontier Province, tend sheep and goats. Some parts of the country have poultry farms. Pakistan exports shrimps, sardines, sharks, and other fish caught in the Arabian Sea.

Service industries employ over 30 percent of Pakistan's work force and contribute about half of its GDP. The service sector has expanded considerably and is especially important in the major cities. Wholesale and retail trade are the largest employers in this sector. Finance, information technology, government, and transportation are other significant service industries.

Manufacturing employs about 18 percent of Pakistan's labor force and contributes about 20 percent of its GDP. Cotton textiles and clothing are the leading manufactured products. Other significant industries include food products, such as flour and sugar; fertilizer and other chemical products; steel; and cement. Craftworkers, operating from home or in small factories, make carpets, embroidered goods, pottery, wooden and leather products, and other handicraft items.

AP/Wide World

Women search for water in the Thar Desert, which lies along Pakistan's southeastern border with India. Much of the Thar is a wasteland, but irrigation has enabled some parts to be farmed.

Energy sources and mining. Fossil fuels, especially coal and petroleum, provide for over two-thirds of Pakistan's energy needs. Hydroelectric power provides the rest. The country imports oil but has rich deposits of natural gas. Salt, coal, chromite, gypsum, iron ore, and limestone are among Pakistan's other mined resources.

International trade. Pakistan's primary exports are textiles, including garments, cotton cloth, and yarn; agricultural products; leather goods; and carpets. Its main imports are petroleum goods, machinery, transportation equipment, and chemicals. Pakistan's chief trading partners are the United States, the United Kingdom, Japan, Germany, Saudi Arabia, and the United Arab Emirates.

Transportation and communication. Railways serve as the principal mode of transportation for passengers and freight in Pakistan. Paved roads link major towns and cities, but motor vehicle travel is limited. In rural areas, camels, cattle, donkeys, and horses provide transportation. Karachi is Pakistan's main seaport. Karachi, Lahore, and Islamabad have international airports.

Pakistan has far more radios than televisions, so radio remains the dominant mode of mass communication. Pakistan has a vibrant newspaper industry. Its publishers produce hundreds of daily newspapers and magazines in Urdu, English, and the regional languages.

History

Early civilizations. Pakistan has a long and complex history, dating back at least 8,000 years to the Mehrgarh civilization in present-day Baluchistan. Later, around 2500 B.C., one of the world's first great civilizations developed in the Indus Valley in what are now Pakistan and northwestern India. Ruins of Harappa and Mohenjo-Daro (also spelled Moenjodaro), the two major cities of the civilization, lie in present-day Pakistan. The ruins show that both cities were large and well-planned. By about 1700 B.C., the Indus Valley civilization had gradually declined. Scholars do not know why it collapsed.

Invasions and conquests. During the next several thousand years, many peoples from southwest and central Asia came into the region that is now Pakistan. About 1500 B.C., a central Asian people called Aryans came through the mountain passes to the Punjab region. In time, they settled across most of India. The Persians conquered the Punjab during the 500's B.C. and made it part of the huge Achaemenid Empire.

In 326 B.C., Alexander the Great of Macedonia took control of most of what is now Pakistan. A few years later, the emperor Chandragupta Maurya made the region part of the Mauryan Empire. The Mauryan Empire began to break up about 230 B.C. Greeks from the independent state of Bactria in central Asia then invaded the Indus Valley. They established a kingdom with capitals near the present-day cities of Peshawar and Rawalpindi.

About 100 B.C., Scythians from Afghanistan came into Baluchistan and Sind. In time, they conquered the Indus region. The Scythians were replaced by the Parthians, who, in turn, were conquered by the Kushans of central Asia. The Kushans ruled what are now Afghanistan, Pakistan, and northwestern India from about A.D. 50 to the mid-200's. They controlled the trade routes from China to India and the Middle East. Peshawar, the Kushan capital, became a commercial center.

During the mid-300's, the Indus Valley became part of

the Gupta Empire, which had expanded westward from northeastern India. Huns from central Asia overran Pakistan during the late 400's.

The Islamic impact. Around A.D. 712, Arab Muslims sailed across the Arabian Sea and invaded Sind, bringing Islam to the region. Beginning about 1000, Muslims invaded northern Pakistan from Iran. Mahmud Ghazni, an Afghan warrior of Turkish descent, established a Muslim kingdom that in time included the entire Indus Valley. Lahore became the capital of the kingdom and developed into a major center of Islamic culture.

In 1206, most of present-day Pakistan came under the control of the Delhi Sultanate, a Muslim empire based in northern India. Under the Delhi Sultanate, a distinctive Indo-Islamic culture developed. The sultanate lasted until 1526, when Babur, a Muslim ruler of Turkish and Mongol descent, invaded India from Afghanistan and founded the Mughal Empire.

The Mughal Empire in time encompassed virtually all of what are now Pakistan, India, and Bangladesh. Under Mughal rule, the Indo-Islamic culture reached its most sophisticated level. It gave rise to a new language, Urdu, which was influenced by both Hindi and Persian. A new religion called Sikhism, which drew upon elements in both Hinduism and Islam, came into being.

In the 1700's, regional rulers acquired greater power at the cost of the central Mughal government. Several groups, including Persians and Afghans, gained control of the region that is now Pakistan. Sikh kingdoms gained strength in the Punjab during the early 1800's, while Sind was ruled by independent Muslim kingdoms.

Colonialism. In the 1500's, European traders began competing for control of the profitable trade between Europe and southern Asia. In the 1600's, after seeking permission from the Mughal emperors, a number of trading companies established settlements along the coastal regions of India. By the mid-1700's, the British East India Company had emerged as the strongest trading power in India. As the Mughal Empire began to break up, the company gradually gained political control over much of India. It fought a series of wars in the Punjab and Sind during the late 1830's and 1840's and added these territories to its holdings.

Resentment of British rule led to many small rebellions and, in 1857, to a widespread uprising. After assisting the British East India Company in crushing the 1857 rebellion, the United Kingdom took control of the company and its territories. Princes controlled the rest of India, and the British made treaty arrangements with these rulers. By 1900, the United Kingdom directly or indirectly controlled all of what is now Pakistan. The territories directly ruled by the United Kingdom were known as British India. See **India** (History [map: British India]).

The British introduced a number of reforms, including a Western system of education. Many Hindus enrolled in the British schools as a way to advance in the colonial system. Some middle- and upper-class Muslims also enrolled, but the majority of Muslims continued to attend their own schools, which stressed religious education. As a result, large numbers of Hindus gained positions in business and government, but the majority of Muslims remained farmers and laborers.

The nationalist movement. The Indian National Congress was formed in 1885 to promote independence for British India. Hindus dominated the organization, and Muslim leaders disagreed on whether or not to cooperate with it. In 1906, some Muslims formed a separate political organization called the All-India Muslim League. The Congress and the Muslim League both sought greater self-government. But differences emerged over how to divide power fairly between Hindus and Muslims. The Muslims feared that Hindus would dominate an independent India.

In 1940, the Muslim League demanded independent Muslim states in northwestern and northeastern India. The president of the Muslim League, Mohammad Ali Jinnah, became the plan's principal supporter. The name *Pakistan,* which means *land of the pure* in Urdu, came to be used for Jinnah's proposed Muslim homelands.

Both the British government and the Indian National Congress rejected the League's demands. To show its strength, the Muslim League declared Aug. 16, 1946, as Direct Action Day. Muslims held nationwide demonstrations calling for the establishment of Pakistan. Violence broke out between Muslims and Hindus. In 1947, hoping to end the violence, the United Kingdom and Hindu leaders agreed to *partition* India—that is, to divide it into separate Hindu and Muslim countries.

Independence. Pakistan became an independent nation on Aug. 14, 1947. The next day, India gained independence. West Pakistan and East Pakistan were carved out of the northwestern and northeastern parts of India, separated by more than 1,000 miles of Indian territory. See **India** (History [map: Independent India]). Jinnah became the first head of state.

Violence between Hindus, Muslims, and Sikhs continued after the partition. Over 10 million people crossed the new borders. Hindus and Sikhs fled to India, and Muslims streamed into Pakistan. Religious riots killed at least half a million people.

Within months of partition, India and Pakistan went to war over Kashmir. A Hindu prince ruled this region, but most of its population was Muslim. When India and Pakistan were partitioned, the prince tried to avoid joining either country. Armed Pakistani tribesmen, backed by government troops, invaded Kashmir to claim it for Pakistan. In response, the prince joined Kashmir to India. Indian and Pakistani troops continued to fight until early 1949, when the United Nations negotiated a cease-fire.

Pakistan became a republic in 1956, but parliamentary elections did not take place as planned. Instead, the military under General Mohammad Ayub Khan assumed control of the state in 1958. Military leaders continued to control the government throughout the 1960's. In 1965, India and Pakistan fought a second war over Kashmir.

Civil war. The people of West and East Pakistan were divided as much by cultural differences as by geography. Only religion united the two groups. West Pakistan controlled the government, economy, and armed forces, which angered East Pakistanis. Bengali-speakers in East Pakistan also resented the government's efforts to impose Urdu as the official language.

In 1970, Pakistan held elections for a National Assembly that would draft a new constitution. East Pakistan had over half of the country's population, so a majority of the Assembly members represented East Pakistan. They hoped to frame a constitution that would give East Pakistan its due share of political and economic power.

In early 1971, Ayub Khan's successor, General Agha Mohammad Yahya Khan, postponed the first meeting of the National Assembly. Infuriated, East Pakistanis took to the streets, prompting a military crackdown. The riots grew into civil war. On March 26, 1971, East Pakistan declared its independence, calling itself Bangladesh. In December 1971, India sent its army to support the rebellion. The war developed into a major conflict with India, and the fighting spread to West Pakistan and Kashmir. On Dec. 16, 1971, Pakistan surrendered. Over a million people died in the fighting.

Yahya Khan resigned, and Zulfikar Ali Bhutto, whose Pakistan People's Party (PPP) held the largest number of seats in West Pakistan, took over as president. He swiftly restored constitutional government and civilian rule.

Struggle for democracy. In 1973, Pakistan adopted its third constitution, which provided for a two-chamber legislature, a president as head of state, and a prime minister as head of government. Bhutto became prime minister and concentrated power in his own hands. In 1977, he called elections in the face of mounting protest against his rule. Bhutto's PPP won the elections, but opponents accused the party of election fraud. Street demonstrations against the government erupted.

In July, General Mohammad Zia-ul-Haq ousted Bhutto from office and declared martial law. Zia assumed the presidency in 1978 while remaining chief martial law administrator. Zia's regime convicted Bhutto of ordering the murder of a political opponent, sentenced him to death, and executed him in 1979.

When the Soviet Union invaded Afghanistan in December 1979, Pakistan's military supported Afghanistan's Islamic resistance fighters. Zia postponed new elections indefinitely and initiated a series of *Islamization* policies, including a system of law enforcement and punishment based on Islamic principles. Many Islamization measures discriminated against women and minorities.

In 1985, Zia allowed new elections to national and provincial assemblies and lifted martial law. However, he also introduced an amendment to the Constitution that gave the president broad powers, including the power to dismiss elected governments and to dissolve parliament. Zia used these powers in 1988 to dismiss the prime minister and dissolve parliament. In August of that year, Zia died in a plane crash.

Muslims board trains to Pakistan after the 1947 *partition* (division) of India along religious lines. Millions of Muslims moved to Pakistan, and millions of Hindus and Sikhs moved to India.

After the Soviets withdrew from Afghanistan in 1989, Pakistan's military continued to support Islamic extremist groups in Afghanistan. Chief among these groups were the Taliban, many of whom were educated in religious schools in the North-West Frontier Province. By the late 1990's, the Taliban controlled most of Afghanistan.

From 1988 to 1999, two parties governed Pakistan alternately—the PPP, led by Benazir Bhutto, the daughter of Zulfikar Ali Bhutto; and the Pakistan Muslim League, led by Mohammad Nawaz Sharif. From 1985 to 1996, three presidents used Zia's constitutional amendment to dismiss four elected governments and parliaments. After the Muslim League won elections in 1997 with a two-thirds majority, Pakistan's legislature repealed the amendment. This reduced the powers of the presidency and made the office of prime minister, then held by Sharif, Pakistan's most powerful government post.

Recent developments. In May 1998, India carried out a series of nuclear tests and declared itself capable of producing and using nuclear weapons. Pakistan responded by conducting its own nuclear tests.

In May 1999, conflict broke out again in Kashmir. Militants backed by Pakistani troops crossed the Kashmiri cease-fire line into Indian-held territory. Fighting then broke out between the militants and Indian troops. In July, under pressure from the United States and other countries, Prime Minister Sharif called for the withdrawal of the Pakistani militants.

In 1999, General Pervez Musharraf led a military coup that overthrew Sharif's government. Musharraf dissolved the parliament and suspended the Constitution. He declared himself the head of a transitional government that included a cabinet and a National Security Council, made up of several Cabinet ministers and the chiefs of staff of the army, navy, and air force. Pakistan's Supreme Court ordered that civilian government be restored by October 2002, and Musharraf agreed to follow the order. Sharif was later exiled to Saudi Arabia. In 2001, Musharraf declared himself president.

Following the September 11 terrorist attacks on the United States, Musharraf allowed U.S. forces to use Pakistani military bases and fly over Pakistani territory in a military campaign against terrorists in Afghanistan. Pakistani supporters of Afghanistan's Taliban government protested against the U.S. attacks and against Musharraf for his support of the United States.

In 2001, armed terrorists attacked India's Parliament, killing or injuring over 20 people, though no elected officials were hurt. India blamed Pakistan for the attack, but Pakistan denied that it had supported the terrorists. The incident led both countries to build up military forces along their shared border. In May 2002, militants in the disputed region of Kashmir attacked Indian outposts there. Troops on both sides exchanged artillery fire, and the two countries seemed on the brink of war.

At Musharraf's request, a referendum was held in April 2002 to extend his term as president for five years.

In August 2002, Musharraf enacted sweeping constitutional changes that cemented his hold on power. Parliamentary elections were scheduled for October 2002.

Palate, *PAL iht,* is the roof of the mouth. The palate has two parts, the *hard palate,* in front, and the *soft palate,* behind. The hard palate is composed of the *palatine* bones and parts of the *maxillary* bones. It is covered with a *mucous membrane.* The soft palate is a fold of muscular tissue covered by epithelial tissue with mucous glands. The palate separates the mouth and the nasal cavity. During swallowing, the soft palate rises and blocks off the rear nasal passage. A projection called the *uvula* hangs from the middle of the soft palate.

WORLD BOOK illustrations by Charles Wellek

The palate, or roof of the mouth, separates the mouth and nasal cavities. It has two parts, *left:* (1) the bony *hard palate* in front, and (2) the muscular *soft palate* in the rear. Both parts are covered by a mucous membrane. The hard palate is formed by parts of the maxillary and palatine bones, *right.*

Only mammals and crocodiles have a palate like that of a human being. In other animals, the base of the skull also serves as the roof of the mouth. Fishes, amphibians, and reptiles may have teeth on the palate. In amphibians, the palate aids in breathing.

Palatinate, *puh LAT uh NAYT,* was the name of two little countries of the old German Empire. The two Palatinates were one political unit until 1620. One was called the Upper Palatinate. The other was called the Lower, or Rhenish, Palatinate. The name *Palatinate* once referred to a castle of the German emperor. The Upper Palatinate is now part of Bavaria. The Lower Palatinate is part of Rhineland-Palatinate. The Lower Palatinate region has fertile soil. It produces good crops of potatoes, tobacco, hemp, flax, wheat, rye, and barley. It has always been noted for its wine. See also **Bavaria.**

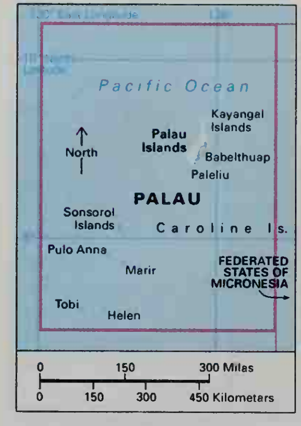
Palau is a small island nation in the western Pacific Ocean. The country is also known as Belau. Palau consists chiefly of about 200 islands in a chain that lies about 500 miles (800 kilometers) east of the Philippines. Palau is part of the Caroline Islands, which belong to a larger island group known as Micronesia.



The United States administered the Palau islands under a United Nations trusteeship called the Trust Territory of the Pacific Islands from 1947 until 1994. That year, Palau became independent. About 20,000 people live in Palau. Koror, on Koror Island, is the capital.

Palau

WORLD BOOK maps

Government. Palau is a republic in *free association* with the United States. Under this arrangement, the Palauan government controls the nation's internal and foreign affairs. However, the United States is responsible for the defense of the islands.

Palau's government is divided into executive, legislative, and judicial branches. The president is elected to a four-year term. Palau has a two-house legislature. Voters elect its 14 senators and 16 delegates every four years. Judges are appointed for life by the president with the consent of the Senate.

People. Most Palauans are descended from the people who originally settled the islands thousands of years ago. About two-thirds of Palau's people live on Koror Island. Most of them work for government agencies. Most of the rest of the islands' people live in scattered rural villages. They farm the land but grow barely enough food to make a small profit. The main foods of Palauans include seafood and *taro,* a plant with a starchy, edible underground stem.

Palauan and English are both official languages of Palau. Palauan children from ages 6 to 14 must attend school. About three-quarters of the people of Palau are Christians. The other one-fourth of the population follow a local religion known as *Modekngei,* which emphasizes traditional Palauan culture and values.

Land and climate. Palau consists mainly of a chain of about 200 islands. The chain extends approximately 100 miles (160 kilometers) from north to south and is about 20 miles (32 kilometers) wide. It is surrounded by a coral reef and is often referred to as the Palau Islands. However, several other scattered islands are also part of Palau. Altogether, Palau has a land area of 177 square miles (459 square kilometers). Babelthuap, also spelled Babeldaob, is Palau's largest island.

The northern islands of Palau are of volcanic origin and have rich soils. Most of these islands are fertile and have many trees. The southern islands are upraised coral formations. Most of these islands are too rugged for people to live on. But they are a major tourist attraction because of their spectacular natural beauty.

Palau has a tropical climate, with daytime temperatures of about 80 °F (27 °C). The islands receive more than 150 inches (380 centimeters) of rain a year.

Economy. The Palauan government provides most jobs and a wide range of social services for the Palauan people. Most of the money for the government operations comes from the United States.

Palau imports finished consumer goods and much of its food. Its chief export is tuna, which is shipped mainly to Japan. Coconut is the chief cash crop. Tourism is becoming an important industry.

History. Archaeological evidence suggests that Palau was one of the first island groups in Micronesia to be settled. The ancestors of the islanders may have arrived from Southeast Asia at least 4,000 years ago.

Spain ruled Palau from 1885 to 1898, when Germany gained control. After Germany's defeat in World War I (1914-1918), Japan administered the islands. Palau became Japan's headquarters for Micronesia, and the islanders were soon outnumbered by Japanese settlers.

After World War II ended in 1945, the Japanese settlers were sent back to Japan. In 1947, the United States began administering the islands as part of the Trust Territory of the Pacific Islands. Palau became a self-governing republic in free association with the United States in October 1994. In December 1994, it became a member of the United Nations. Robert C. Kiste

Paleobotany, *PAY lee oh BAHT uh nee,* is the study of ancient plants. Paleobotany is a branch of *paleontology,* the study of ancient plants, animals, and other organisms. Specialists called *paleobotanists* investigate the evolution of plant life and the origins and relationships of plant groups. They also examine the link between vegetation and the earth's changing climate. Paleobotany includes the study of such simple organisms as ancient algae, fungi, and bacteria. In addition, it involves searching for the earliest evidence of life in rocks more than 3 billion years old.

Paleobotanists interpret the earth's history by examining plant fossils. These fossils have been preserved in *sedimentary rocks* (rocks formed from deposits laid down by ancient rivers, lakes, and seas). Paleobotanists have found the earliest land plants in sedimentary rocks that are more than 430 million years old. Remains of early forests are abundant in rocks 350 million years old. The ancestors of all major groups of land plants lived in these forests. Today, the most numerous plants on earth are *angiosperms* (flowering plants). Paleobotanists have discovered that the first angiosperms appeared about 140 million years ago, during the age of the dinosaurs.

Paleobotanists study the features that plants have developed to survive in their environment. These scientists are thus able to describe the type of climate that existed millions of years ago. Paleobotany contributes to an understanding of how and why the earth's climate changes. This understanding is important in predicting the changes in climate that humans may cause through the *greenhouse effect* (a gradual warming of the earth's surface). James F. Basinger

Paleogeography. See Paleontology.

Paleography, *PAY lee AHG ruh fee,* is the study of ancient and medieval handwriting. It deals mainly with writing on perishable materials, such as papyrus, parchment, or paper. A related field called *epigraphy* is the study of writing cut in more permanent material, such as metal or stone.

Specialists called *paleographers* study and translate ancient and medieval writings. They carefully examine the shape of the letters and the abbreviations used. They classify various writing styles and trace their historical development. With these techniques, paleographers can identify where and when unsigned and undated manuscripts probably were written.

Medieval styles of handwriting included *book hands,* also called *formal hands; documentary hands,* also called *diplomatic* or *informal hands;* and *national hands.* Book hands were made up of capital and small letters. Documentary hands consisted of flowing writing with the letters joined together. National hands differed according to geographical areas. A style called *Gothic script* or *black letter,* which had heavy lines, became widely used in Europe between the 1100's and the 1500's. *Humanistic script* was popular in Europe in the 1500's and the 1600's. It consisted of two styles that resembled Roman and italic type. These words are set in Roman type, and *these words are in italic type.*

Paleographers study writing that dates up to the 1600's. By that time, printed works had replaced most handwritten manuscripts. Jean Mabillon, a French monk, wrote what was probably the first book on paleography, *De re diplomatica,* in 1681. Julian G. Plante

Paleolithic Period. See Stone Age.

Paleontology, *PAY lee ahn TAHL uh jee,* is the study of animals, plants, and other organisms that lived in prehistoric times (more than 5,500 years ago). Fossil remains of organisms occur in layers of *sedimentary rocks* (rocks formed when mineral matter settled out of air, ice, or water). The organisms that are now fossils were alive when the rocks were being formed. They were buried and preserved as the layers of rock piled up.

By studying fossils, paleontologists learn what kind of life existed in various periods of the earth's history. The oldest known fossils are bacteria that lived about $3\frac{1}{2}$ billion years ago. The fossil record shows a gradual increase in the complexity of animals and plants. This gradual change in body form is called *evolution.*

Paleontology is important in the study of geology. The age of rocks may be determined by the fossils in them. Fossils also tell whether rocks were formed under the ocean or on land. Most rocks that contain marine shell fossils were formed under the ocean. Most rocks that contain land animal and land plant fossils were formed on land. The knowledge of where rocks were formed helps scientists map the world as it was millions of years ago. Such scientists are called *paleogeographers.*

Paleontology aids in the location of oil. Oil is often found in rocks that contain certain fossils. Oil companies use such fossils as a clue to where to find oil.

There are three main branches of paleontology: (1) invertebrate paleontology, (2) vertebrate paleontology, and (3) paleobotany. Invertebrate paleontology deals with fossil *invertebrates* (animals without backbones), such as mollusks and corals. Vertebrate paleontology is concerned with extinct fishes, amphibians, reptiles, birds, and mammals. Paleobotany is the study of fossil plants. Michael R. Voorhies

Palermo, *puh LUR moh* or *puh LAIR moh* (pop. 698,556), is the capital and chief seaport of Sicily, an Italian island. It lies along the Tyrrhenian Sea in northwestern Sicily (see **Italy** [political map]). Palermo is a center of industry and trade. Produce from nearby farms is sold or processed there. Palermo exports agricultural products, including canned foods, citrus fruits, and wines. Industries include fishing and the manufacture of furniture, glass, steel, and textiles. People visit Palermo to see its museum, churches, and palaces. The city is the home of the University of Palermo. Modern suburbs surround the city's older section.

The Phoenicians founded Palermo between the 600's and 500's B.C. Muslims captured the city in A.D. 831. Under their rule, Palermo became a center of trade and culture. The Normans conquered the city in 1072 and made it the capital of the kingdom of Sicily. Several countries held Palermo before it became part of Italy in 1860. David I. Kertzer

Palestine, *PAL uh STYN,* a small, historic land at the eastern end of the Mediterranean Sea, is one of the world's most historic places. Two great religions—Judaism and Christianity—originated in Palestine. It is the Holy Land, the site of many events described in the Bible. Muslims, the followers of the Islamic religion, also consider Palestine a sacred place.

The Land of Canaan about 1000 B.C.

Most of the Land of Canaan, later called Palestine, was held by the Twelve Tribes of Israel. The names of these tribes are listed below, and their areas are shown by number on the map.

Palestine's location between Egypt and southwest Asia has made it a center of conflict for thousands of years. Many peoples have invaded the region, and there has never been an independent state of Palestine. In the 400 years before World War I (1914-1918), Palestine was part of the Ottoman Empire. After the war, Palestine came under British control. Both the Arab and Jewish inhabitants of Palestine fought for control of the territory. Following a war in 1948 and 1949 between Arabs and Jews, Palestine was divided among Israel, Jordan, and Egypt. Many of Palestine's residents became refugees. Conflicts over Palestine continued between Arabs and Jews after the war. For details, see *The continuing conflict and peace efforts* section of this article.

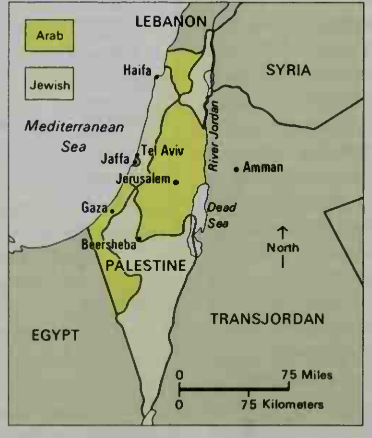
Early history and settlement. Amorites, Canaanites, and other Semitic peoples entered the area about 2000 B.C. The area became known as the Land of Canaan. Sometime between about 1800 and 1500 B.C., a Semitic people called Hebrews left Mesopotamia and settled in Canaan, where they became known as Israelites. Some of these Israelites later went to Egypt. In the 1200's B.C., Moses led the Israelites out of Egypt, and they returned to Canaan. The Israelites practiced a religion centered on the belief in one God. Other peoples in Canaan worshiped many gods.

For about 200 years, the Israelites fought the other peoples of Canaan and the neighboring areas. One of their strongest enemies, the Philistines, controlled the southwestern coast of Canaan—called Philistia.

Until about 1029 B.C., the Israelites were loosely organized into 12 tribes. The constant warfare with neighboring peoples led the Israelites to choose a king, Saul, as their leader. Saul's successor, David, unified the nation to form the Kingdom of Israel, about 1000 B.C. David established his capital in Jerusalem. His son, Solomon, succeeded him as king and built the first Temple for the worship of God. Israel remained united until Solomon's death about 928 B.C. The northern tribes of Israel then split away from the tribes in the south. The northern state continued to be called Israel. The southern state, called Judah, kept Jerusalem as its capital. The word *Jew,* which came to be used for all Israelites, comes from the name *Judah.*

Invasions and conquests. During the 700's B.C., the Assyrians, a people who lived in what is now Iraq, extended their rule westward to the Mediterranean Sea. They conquered Israel in 722 or 721 B.C. After about 100 years, the Babylonians began to take over the Assyrian Empire. They conquered Judah in 587 or 586 B.C. and destroyed Solomon's Temple in Jerusalem. They enslaved many Jews and forced them to live in exile in Babylonia. About 50 years later, the Persian king Cyrus conquered Babylonia. Cyrus allowed a group of Jews from Babylonia to rebuild and settle in Jerusalem.

The Persians ruled most of the Middle East, including Palestine, from about 530 to 331 B.C. Alexander the Great then conquered the Persian Empire. After Alexander's death in 323 B.C., his generals divided his empire. One of these generals, Seleucus, founded a *dynasty* (series of rulers) that gained control of much of Palestine about 200 B.C. At first, the new rulers, called Seleucids, allowed the practice of Judaism. But later, one of the kings, Antiochus IV, tried to prohibit it. In 167 B.C., the Jews revolted under the leadership of the Maccabeans and drove the Seleucids out of Palestine. The Jews reestablished an independent kingdom called Judah.



Roman rule. In 63 B.C., Roman troops invaded Judah, and it came under Roman control. The Romans called the area Judea. Jesus Christ was born in Bethlehem in the early years of Roman rule. Roman rulers put down Jewish revolts in A.D. 66 and A.D. 132. In A.D. 135, the Romans drove the Jews out of Jerusalem. The Romans named the area Palaestina, for Philistia, at about this time. The name *Palaestina* became *Palestine* in English.

Most of the Jews fled from Palestine. But Jewish communities continued to exist in Galilee, the northernmost

Palestine These maps show important stages in Palestine since World War I (1914-1918). In 1920, Palestine—previously part of the Ottoman Empire—became a mandated territory of the United Kingdom. The establishment of Israel in 1948 increased the conflicts between Arabs and Jews in the area.

The British mandate of Palestine is shown here as it existed in 1922. From 1920 to 1922, the mandate also included the Transjordan mandate to the east.

The United Nations partition plan of 1947 divided Palestine into Arab and Jewish areas. The Jewish area became the independent nation of Israel in 1948.

part of Palestine. Palestine was governed by the Roman Empire until the A.D. 300's and then by the Byzantine Empire. In time, Christianity spread to most of Palestine.

Arab control. During the A.D. 600's, Muslim Arab armies moved north from Arabia to conquer most of the Middle East, including Palestine. Muslim powers controlled the region until the early 1900's. The rulers allowed Christians and Jews to keep their religions. However, most of the local population gradually accepted Islam and the Arab-Islamic culture of their rulers.

In the 1000's, the Seljuks, a Turkish people, began to take over Palestine. They gained control of Jerusalem in 1071. Seljuk rule of Palestine lasted less than 30 years. Christian crusaders from Europe wanted to regain the land where their religion began. The Crusades started in 1096. The Christians captured Jerusalem in 1099. They held the city until 1187, when the Muslim ruler Saladin attacked Palestine and took control of Jerusalem.

In the mid-1200's, Mamelukes based in Egypt established an empire that in time included Palestine. Arab Muslims made up most of Palestine's population. Beginning in the late 1300's, Jews from Spain and other Mediterranean lands settled in Jerusalem and other parts of Palestine. The Ottoman Empire defeated the Mamelukes in 1516, and Palestine became part of the Ottoman Empire. The Jewish population slowly increased, and by 1880, about 24,000 Jews were living in Palestine.

The Zionist movement. Beginning in the late 1800's, oppression of Jews in Eastern Europe set off a mass emigration of Jewish refugees. Some Jews formed a movement called *Zionism,* which sought to make Palestine an independent Jewish nation. The Zionists established farm colonies in Palestine. At the same time, Palestine's Arab population grew rapidly. By 1914, the total population of Palestine stood at 700,000. About 615,000 people were Arabs, and 85,000 were Jews.

World War I and the Balfour Declaration. During World War I (1914-1918), the Ottoman Empire joined Germany and Austria-Hungary against the Allies. An Ottoman military government ruled Palestine. Britain and some of the European Allies planned to divide the Ottoman Empire among themselves after the war. The Sykes-Picot Agreement of 1916 called for part of Palestine to be placed under a joint Allied government. Britain offered to back Arab demands for postwar independence from the Ottomans in return for Arab support for the Allies. In 1916, some Arabs revolted against the Ottomans in the belief that Britain would help establish Arab independence in the Middle East. The Arabs later claimed that Palestine was included in the area promised to them, but the British denied this.

In 1917, in an attempt to gain Jewish support for its war effort, Britain issued the Balfour Declaration. The declaration stated Britain's support for the creation of a Jewish national home in Palestine, without violating the civil and religious rights of the existing non-Jewish communities.

After the war, the League of Nations divided much of the Ottoman Empire into *mandated territories* (see **Mandated territory**). In 1920, Britain received a provisional mandate over Palestine, which would extend west and east of the Jordan River. The British were to help the Jews build a national home and promote the creation of self-governing institutions. In 1922, the League declared that the boundary of Palestine would be limited to the area west of the river. The area east of the river, called Transjordan (now Jordan), was made a separate British mandate. The two mandates took effect in 1923.

The terms of the Palestine mandate were not clear, and various parties interpreted it differently. Many Zionists believed that Britain did not do enough to promote a Jewish national home. They especially opposed restrictions set by the British on Jewish immigration and land purchases. The British hoped to establish self-governing institutions, as required by the mandate. But their proposals for such institutions were unacceptable to the Arabs, and so none were created.

The Arabs opposed the idea of a Jewish national home. They feared that the British were handing Palestine over to the Zionists by allowing too many Jews to immigrate to Palestine. During this period, a Palestinian Arab national movement first appeared. On several occasions, riots and demonstrations were mounted by the Arabs to protest British policies and Zionist activities.

In the early 1930's, over 100,000 Jewish refugees came to Palestine from Nazi Germany and Poland. This development alarmed the Palestinian Arabs. The Arabs organized a general uprising that almost paralyzed Palestine during the late 1930's. In 1939, the British began to drastically limit Jewish immigration and land purchases for the next five years. Any Jewish immigration after that would depend on Arab approval.

World War II and the division of Palestine. During World War II (1939-1945), many Palestinian Arabs and Jews joined the Allied forces. After the war, the Zionists used force to stop Britain from limiting Jewish immigration into Palestine. The Zionists wanted the British to allow immigration of several hundred thousand Jewish survivors of the *Holocaust,* the mass murder of European Jews and others by the Nazis.

The United Nations Special Commission on Palestine recommended that Palestine be divided into an Arab state and a Jewish state. The commission called for Jerusalem to be put under international control. The UN General Assembly adopted this plan on Nov. 29, 1947. The Jews accepted the UN decision, but the Arabs rejected it. Fighting broke out immediately.

On May 14, 1948, the Jews proclaimed the independent state of Israel, and the British withdrew from Palestine. The next day, neighboring Arab nations attacked Israel. When the fighting ended in 1949, Israel held territories beyond the boundaries set by the UN plan. The rest of the area assigned to the Arab state was occupied by Egypt and Jordan. Egypt held the Gaza Strip and Jordan held the West Bank. About 700,000 Arabs fled or were driven out of Israel and became refugees in neighboring Arab countries.

The continuing conflict and peace efforts. The UN arranged a series of cease-fires between the Arabs and the Jews in 1948 and 1949. Full-scale wars broke out again in 1956 and 1967. By the time the UN cease-fire ended the 1967 war, Israel had occupied the Gaza Strip and the West Bank. Israel also held Egypt's Sinai Peninsula and Syria's Golan Heights. In October 1973, Egypt and Syria launched a war against Israel. Cease-fires ended most of the fighting within a month.

The 1967 war brought about a million Palestinian Arabs under Israeli rule. After the war, the fate of the

Palestinians played a large role in the Arab-Israeli struggle. In time, the Palestine Liberation Organization (PLO) became recognized by all the Arab states as the representative of the Palestinian people. Israel strongly opposed the PLO because of its terrorist acts against Jews.

In 1978, Egypt and Israel signed an agreement designed to settle their disputes. Israel withdrew from the Sinai Peninsula in 1982. The agreement included provisions for a five-year period of self-government for the residents of the Gaza Strip and the West Bank. This period was to be followed by a decision about the future status of these territories. But no arrangement for such self-government was made following the agreement.

Beginning in 1987, Arabs in the Gaza Strip and West Bank staged several violent protests that became known as the first *intifada,* which means *uprising* in Arabic. Israeli troops killed a number of protesters. In the 1990's, Israel and the PLO signed agreements that led to the withdrawal of Israeli troops from the Gaza Strip and parts of the West Bank. As the Israelis withdrew, Palestinians took control of these areas. In 1996, Palestinians in these areas elected a legislature and president.

Peace talks between Israeli and Palestinian leaders continued in 2000, but the two sides could not agree on key issues. That year, Palestinians began a second intifada. Attacks by Palestinian militias and suicide bombers took place throughout Israel, the West Bank, and the Gaza Strip, killing hundreds of Israelis. Israeli forces repeatedly bombed and invaded the West Bank and Gaza Strip, killing more than 1,700 Palestinians. In 2002, Israel reoccupied much of the West Bank. Michel Le Gall

Palestine Liberation Organization (PLO) is the political body that represents the Arab people of Palestine. Its chief goal is to establish a state in Palestine for these Arabs. Palestine is a historic region that now consists of Israel, the West Bank, and the Gaza Strip.

About 700,000 Palestinian Arabs became refugees as a result of the Arab-Israeli war of 1948, when the state of Israel was founded. Today, there are more than 8 million Palestinian Arabs. More than 4 million of them live outside what was Palestine. The PLO includes guerrilla groups and associations of doctors, laborers, lawyers, women, students, and teachers. A number of Palestinian Arabs are independent members of the PLO. Guerrilla groups, primarily *Al Fatah,* dominate the organization.

Organization. The main organs of the PLO are the Executive Committee, the Central Committee, and the Palestine National Council. The Executive Committee is the main decision-making body. It consists of representatives of the major guerrilla groups and some independent members. The Central Committee, which includes representatives of all guerrilla groups, acts as an advisory group to the Executive Committee. The Palestine National Council, which has about 180 members, serves as the assembly of the Palestinian people.

History. The PLO was founded in 1964. In 1974, the Arab governments and the United Nations (UN) recognized the PLO as the representative of the Palestinian Arabs. The PLO did not recognize Israel's right to exist.

Since the 1960's, PLO guerrilla groups have staged attacks against Israel from time to time. Israel, in turn, has attacked PLO bases. From 1965 to 1971, the PLO operated from Jordan, where it also challenged the rule of King Hussein of Jordan. But Jordanian army forces drove out the PLO in 1970 and 1971. The PLO then moved to Lebanon and continued to attack Israel. In 1982, Israel drove the PLO out of southern Lebanon and Beirut. After Israeli troops withdrew from most of Lebanon in 1985, some PLO members returned to southern Lebanon.

Yasir Arafat became PLO chairman in 1969. In 1983, Syria supported rebels within the PLO who opposed Arafat's leadership. The rebels drove Arafat and his PLO forces out of northern Lebanon. In the mid-1980's, the PLO was seriously weakened by its internal conflicts, Israeli opposition, and conflicts with important Arab governments. But the Palestinian people and most Arab governments continued to support Arafat and the PLO.

In 1987, Palestinians in the West Bank and Gaza Strip began violent protests known as the first *intifada.* The PLO supported the Palestinians. Israeli troops assassinated the top PLO official responsible for the support.

Until 1988, Jordan provided the West Bank with financial and administrative support. But in July of that year, King Hussein announced that his country would end its support. He called on the PLO to take over Jordan's role in the West Bank. In late 1988, Arafat announced the PLO's recognition of Israel's right to exist alongside a Palestinian state. He renounced the use of terrorism. But some PLO members opposed to Arafat continued to launch terrorist attacks against Israeli targets.

In 1991, the Lebanese Army defeated PLO forces in southern Lebanon. Afterward, most PLO members left their military bases there, but the PLO continues to have influence in Palestinian refugee camps in Lebanon.

Peace talks between Israel, a number of Arab countries, and the Palestinians began in late 1991. Only Palestinians from the occupied territories were allowed to participate. PLO leaders advised the Palestinians during the talks. But separate discussions between the PLO and Israel took place. In 1993, the PLO and Israel recognized each other and signed an agreement that included steps to end their conflicts. As a result of this and later agreements, Israel withdrew from most of the Gaza Strip and parts of the West Bank. As the Israelis withdrew, Palestinians took control of these areas. In 1996, Palestinians in these areas elected a legislature and a president. Arafat was elected president of the new Palestinian Authority. Though the PLO continues to function as the representative of the entire Palestinian people, the Palestinian Authority has gained influence at the PLO's expense.

Peace talks between Israeli and Palestinian leaders in 2000 failed to resolve key remaining issues between the two sides. That year, Palestinians began another intifada. Attacks by Palestinian militias and suicide bombers took place throughout Israel, the West Bank, and the Gaza Strip, killing hundreds of Israelis. Israeli forces repeatedly bombed and invaded the West Bank and Gaza Strip, killing more than 1,700 Palestinians. In 2002, Israel reoccupied much of the West Bank. Michael C. Hudson

Palestinians are an ethnic and national group native to the historic region of Palestine that now consists of Israel, the West Bank, and the Gaza Strip. Today, there are about 8 million Palestinians. Nearly half now live outside what was Palestine—in nearby Arab countries and elsewhere. Most of these Palestinians are refugees or the descendants of the more than 700,000 refugees who fled or were driven out of Israel when it was created in 1948. Some are people who were forced to leave the Gaza Strip and the West Bank, which were occupied by Israel in 1967. Today, though some Palestinians still live in refugee camps, most have integrated socially and economically within the host countries.

Modern Palestinians claim to be descendants of the *Philistines,* an ancient people who settled the region near the end of the 1200's B.C., and other groups who arrived later. Arab culture became a dominant influence beginning about A.D. 638 , when Muslim Arabs conquered much of the region. Palestinians today speak Arabic with regional accents that distinguish them from other Arab groups. Nearly all Palestinians are Muslims, with a large Christian minority.

The Palestinian people began to develop a modern national identity around 1900. Palestinian national identity has a number of sources. It comes in part from the religious attachment of Muslims and Christians to Palestine as a holy land. Palestinian nationalism and the desire for self-determination also developed as a response to *Zionism,* a movement that began in the 1800's and called for a Jewish national state in Palestine. In 1947, the United Nations voted to partition Palestine into a Jewish state and an Arab state. Jerusalem was put under international control. The Jews in Palestine accepted this plan, but the Arabs rejected it. Israel came into existence in 1948. War quickly broke out between Israel and the surrounding Arab countries. By 1949, Israel had won the war and taken control of about half the land planned for the new Arab state. Egypt and Jordan held the rest of Palestine. These areas came under Israeli control in 1967.

Today, Palestinians hold a variety of professional positions and are an important part of the economies of several Middle Eastern countries. About 2 million Palestinians are citizens of Jordan. Many others carry passports from the Palestinian Authority, which is the political body that administers Palestinian-controlled portions of the Gaza Strip and West Bank. About 1 million Palestinians are citizens of Israel, where they are subject to discrimination and many legal restrictions. Many Palestinians in Lebanon, Syria, and Egypt remain stateless refugees with no citizenship. Rashid I. Khalidi

Palestrina, *PAL uhs TREE nuh* or *PAH lay STREE nah,* **Giovanni,** *joh VAHN nee* (1525?-1594), was one of the greatest composers of the Italian Renaissance. For the Roman Catholic Church, Palestrina wrote about 250 unaccompanied choral works called *motets,* and 93 masses. Two of his most famous works are the mass called *Missa Papae Marcelli* (about 1562) and his setting of the *Stabat Mater* (about 1563). He also composed unaccompanied nonreligious choral pieces called *madrigals.* The most famous is *Vestiva i colli* (1566).

Palestrina was a master of the *polyphonic* style of music, in which each voice has a separate melody. In his music, the voices imitate each other in graceful melodic curves, maintaining a steady rhythm. For contrast, the choir sometimes sings together in chords.

Palestrina took his name from his birthplace, the town of Palestrina, near Rome. His full name was Giovanni Pierluigi da Palestrina. Joscelyn Godwin

Palladio, *pahl LAH dyoh,* **Andrea,** *ahn DREH ah* (1508-1580), was an architect of the Italian Renaissance. He visited Rome frequently between 1541 and 1554, and he developed a great interest in and knowledge of ancient Roman architecture. That influence appears in his *Four Books of Architecture* (1570), an important work of Renaissance architectural theory. It also appears in his architectural works, notably in the Basilica in Vicenza (begun about 1547) and the Villa Rotonda (begun about 1567) near Vicenza. Palladio influenced architect Inigo

A Palladio church in Venice called San Giorgio Maggiore was designed in 1565 and completed in 1610, after the architect's death. The *facade* (front) features four giant columns topped by a triangular pediment in the style of an ancient Roman temple.

Jones in England in the 1600's and Georgian architecture in England in the 1700's and in the United States in the late 1700's and early 1800's. Palladio's influence reappeared in the late 1900's in a movement in Europe and the United States called Postmodernism.

Palladio was born on Nov. 30, 1508, in Padua. His real name was Andrea di Pietro della Gondola. The Italian scholar Giangiorgio Trissino named him Palladio after Pallas Athena, the Greek goddess of wisdom.

Palladium, *puh LAY dee uhm,* is a soft, shiny, silvery-white metal. It is one of six platinum metals, and is relatively rare. Palladium is often used in place of platinum because it is cheaper, harder, and lighter than platinum. It is found with deposits of other platinum metals, with nickel-copper ores, and with mercury.

Palladium can be drawn into wire or hammered into sheets. It is often mixed with gold to make "white gold" jewelry. It is also used to make surgical instruments.

Finely divided palladium, called *palladium black,* is used as a *catalyst,* a substance that causes or speeds up chemical changes. It is an important catalyst in a process called *hydrogenation,* which is used to improve the quality of oils and to prepare gasoline. Automakers use palladium, together with platinum and rhodium, in *catalytic converters.* These devices reduce the pollutants given off by auto engines (see **Catalytic converter**).

The English chemist William H. Wollaston discovered palladium in 1803. Its *atomic number* (number of protons in its nucleus) is 46. Its *relative atomic mass* is 106.42. A chemical element's relative atomic mass equals its *mass* (amount of matter) divided by $\frac{1}{12}$ of the mass of carbon 12, the most abundant form of carbon. Palladium melts at 1552 °C and boils at 2940 °C. Its density is 11.99 grams per cubic centimeter at 20 °C. S. C. Cummings

Palliative care is medical care provided to people dying of an incurable illness. Such care differs from *curative medicine,* which focuses on restoring health, or treatments for chronic illness, referred to as *supportive medicine.* The goal of palliative care is to provide comfort for the patient's remaining life and a peaceful death. Palliative care focuses on relieving the symptoms, particularly pain, of incurable illness. It also addresses the psychological, social, and spiritual needs of the patient, and provides support for the patient's family and caregivers.

Palliative care differs from physician-assisted suicide or *euthanasia* (helping or allowing people to die). It is not intended to be the direct cause of death. Supporters of palliative care believe that many terminally ill patients ask to die because they suffer from untreated pain, undiagnosed depression, despair, or social isolation. Medical studies have shown that dying patients often do not receive adequate treatment for pain and depression.

In palliative care, the caregivers acknowledge dying as a normal process and death as part of life. Once the medical team deems a patient's condition terminal, they turn away from attempts at cure and towards making the patient feel comfortable and ready to die peacefully. Hospice care is a form of palliative care.

Palm is a group of trees, vines, and shrubs that typically grow in warm and wet climates, especially in the tropics. Palms are among the most important plants in tropical regions because they provide food, drink, fibers, and building materials for the people.

Palms are most diverse and most common in Southeast Asia, the Pacific islands, and in tropical America. They grow wild as far north as Korea, Japan, and the states of North Carolina and California in the United States; and as far south as Argentina, central Chile, New Zealand, and South Africa. They also are cultivated on plantations in many tropical regions. Some palms live more than 100 years.

Palms are an ancient group of plants. Fossils of palm leaves have been found that date from the Age of Reptiles. Palms once grew in all parts of the world, and palm fossils have been found as far north as Greenland.

Kinds of palms. There are more than 2,800 kinds of palms, and they vary greatly in size and the kind of flowers, leaves, and fruits they produce. Most palms grow straight and tall. But the trunks of some palms may lie on the ground. Some have most of the trunk buried in the soil. The rattan palms found in the jungles of Southeast

Most palms have a branchless trunk topped by a leafy crown. Canary Island date palms, *left,* have an especially dense crown. The trunk of the Washingtonia palm, *center,* is partly covered by a "skirt" of dead leaves. Royal palms, *right,* have a whitish trunk that resembles a concrete pillar.

Asia have slender, vinelike stems from 10 to 250 feet (3 to 76 meters) long. The stems may trail along the jungle floor or climb high in the trees. Most palms have a single trunk or stem. But many have clustered trunks that grow from the same root base.

The trunk is usually straight and round and from 4 to 24 inches (10 to 61 centimeters) thick. But some palms have trunks that are no thicker than a pencil, while others have trunks that are 5 feet (1.5 meters) thick. The trunk may range from a few inches or centimeters to well over 100 feet (30 meters) tall. The trunks of the larger palm trees grow from 1 to 4 feet (30 to 120 centimeters) a year. The trunk may have rough or smooth bark, and some have thorns. Only a few palms have branches growing from the trunk. A few kinds have a strawlike "skirt" of dead leaves that hangs down along the trunk. Most palms have their fanlike or featherlike leaves clustered at the top of the trunk.

The leaves vary greatly in size and appearance. The smallest leaves are less than 1 foot (30 centimeters) long. Most of the fanlike leaves are from 2 to 4 feet (60 to 120 centimeters) wide, and the featherlike types may be 20 feet (6 meters) long and from 1 to 4 feet (30 to 120 centimeters) wide. Two types produce the largest leaves. The talipot palm has fan-shaped leaves that may be 15 feet (4.6 meters) wide. The raffia palm's leaves may be 65 feet (20 meters) long and 8 feet (2.4 meters) wide. Mature leaves remain on a palm from one to nine years.

The fruits differ greatly in size and shape. Some fruits are no larger than a pea. The huge fruit of the double coconut palm may grow as large as 2 feet (60 centimeters) in diameter. The fruit of the palm contains from one to seven seeds. The flesh of the fruit may be soft, as in the date, or firm and threadlike, as in the coconut. The seed may be hard, as in the date. Only rarely is it soft, or even hollow and filled with "milk," as in the coconut. The double coconut and the true coconut have the largest of all known seeds. The male and female flowers of many kinds of palms are on different trees and depend on people, wind, or insects for fertilization.

Products of palms. Palms provide ornament, shade, building materials—both timbers and thatch—and fuel. Fibers for making ropes and brooms and for *caulking* (making watertight) ships are made from the palm. Strips of leaves are woven into mats, hats, and baskets. Oil for food and lighting comes from several species, particularly the oil palm. The sugary sap of such palms as the palmyra palm can be made into food, sweet drinks, and intoxicating beverages, such as *arak* (also spelled *arrack*). The starch of palms is used for food. The seeds are crafted into buttons and carvings. People chew betel palm seeds as a stimulant. A few palms have poisonous seeds.

The palm is most important to the people who live in the tropics. But people elsewhere also depend on palms for many useful products. The dried oily meat of the coconut is used to add flavor to cakes. Its rich oil is used in soap, salad oils, cooking fats, and margarine. Oil from the oil palm is used in cosmetics and in pharmaceutical creams and ointments. Dates are a familiar product of the date palm. Sago is a starch taken from palm trunks.

Many baskets and chair bottoms are woven from strips of palm leaves. The stems of the rattan palm are used in making furniture. Raffia is made of thin layers of cells stripped from the leaves of a Madagascar palm. It is used by children in basket making at school. Wax from the leaves of the carnauba palm of Brazil is used in such products as shoe polish. Michael G. Barbour

Scientific classification. Palms belong to the palm family, Palmae, also called Arecaceae.

Palm oil, made from the fruit of the oil palm tree, is a widely used vegetable oil. Taken together, palm oil and soybean oil account for about half of all vegetable oils produced throughout the world. Palm oil is used in making a variety of products, including ice cream, cooking oil, margarine, shortening, and soap.

The fruit of the oil palm tree is reddish-orange and about the size of a date. The tree produces 10 to 15 fruit clusters, each with about 200 fruits. The clusters are cut from the trees and taken by truck to a mill, where they are sterilized and separated into individual fruits. A machine called a *digester* converts the fruit into a mash, which is crushed to obtain crude palm oil. The crude oil is then dehydrated, cleaned, and refined.

During the 1700's, the English used palm oil as a medicine and hand cream. In the early 1900's, oil palm trees were planted in parts of Africa. Many rubber plantations in Indonesia and Malaysia were replanted with oil palms during the 1960's. Today, the two countries produce the majority of the world's palm oil. David E. Zimmer

Palm Springs (pop. 41,155) is a resort city in southern California surrounded by desert land and mountains. For location, see **California** (political map). The city is named for the palm trees that line its streets and its natural hot springs. These features—plus a warm climate, fashionable hotels and private houses, golf courses, and swimming pools—make Palm Springs a major tourist attraction. The Palm Springs Aerial Tramway carries passengers to near the top of nearby Mount San Jacinto.

About a fifth of the city's area is part of a reservation of the Agua Caliente Band of Cahuilla Indians. The Indians lived in the area long before it was settled by whites in the late 1800's. In the 1930's, Palm Springs became a popular resort for movie stars. The city has a council-manager form of government. James J. Rawls

Palm Sunday is the Sunday before Easter and the beginning of Holy Week in the Christian calendar. Palm Sunday worship recalls when people spread palms and clothing in front of Jesus as He entered Jerusalem. This procession took place several days before He was crucified. Palm Sunday marks a turn in Christian churches' observance of Lent from a time of discipline and sorrow for one's sins to a time of looking ahead to the *Passion* (suffering and death) of Jesus and His Resurrection.

By the late 300's, Christians in Jerusalem were celebrating Palm Sunday on the first day of Holy Week. It was part of a trend there to remember the last events of Jesus's life by holding services at sacred sites in the city. Today, Christians in many traditions observe Palm Sunday with the blessing and distribution of palms. Usually,

the ceremony includes a procession. David G. Truemper

Palmares, *puhl MAH rihs,* was the largest and most famous community established by runaway slaves in Brazil during the 1600's. Through the years, it has become an important symbol of the black struggle for freedom in Brazil and other parts of the Americas.

Palmares was formed about 1605 and grew through the union of several *mocambos*—that is, settlements of runaway slaves. It lay in a rugged area of what is now northeastern Brazil. Eventually, Palmares was organized like an African kingdom, with a powerful elected king. Several relatives helped the king rule the community.

Palmares was composed primarily of African-born people from several ethnic groups, but it also attracted blacks born in Brazil. Estimates of the size of Palmares vary, but the kingdom was home to 11,000 to 20,000 people at its peak. The people of Palmares hunted and fished. They grew a variety of crops, including bananas, beans, cassava, corn, sweet potatoes, and sugar cane. They were skilled at various crafts, including pottery making, woodworking, and weaving.

Palmares withstood attacks from the Dutch, who took control of Brazil from Portugal in 1630, and from the Portuguese, who regained the colony in 1654. The Portuguese attacked almost annually from 1672 to 1694, when they finally destroyed the kingdom. Colin A. Palmer

Palmer, A. Mitchell (1872-1936), served as United States attorney general from 1919 to 1921 under President Woodrow Wilson. Palmer is best known for the *Palmer Raids* of January 1920, in which thousands of suspected anarchists and Communists were jailed with little regard for their constitutional rights. Many historians believe Palmer hoped to win the 1920 Democratic presidential nomination by capitalizing on the antiradical feelings that many Americans held at that time.

Alexander Mitchell Palmer was born on May 4, 1872, in Moosehead, Pennsylvania. He served in the U.S. House of Representatives from 1909 to 1915. As a member of the Democratic national committee in 1912, he helped Wilson win the presidential nomination.

Palmer, Alice Elvira Freeman (1855-1902), gained fame as an American educator. In 1879, at the age of 24, she became head of the history department at Wellesley College. Three years later, she became president of Wellesley. She was one of the youngest college presidents in history. She resigned as president in 1887 after she married George Herbert Palmer, a Harvard University professor. She served as the first dean of women at the University of Chicago from 1892 to 1895.

In 1882, she helped organize the Association of Collegiate Alumnae, which later became the American Association of University Women. She served as its president in 1885 and 1886. Alice Elvira Freeman was born on Feb. 21, 1855, in Colesville, New York. Nancy Woloch

Palmer, Arnold (1929-), an American golfer, became one of the greatest and most popular players in the history of the sport. Palmer was the first player to win the Masters Tournament four times—in 1958, 1960, 1962, and 1964. Palmer's appealing personality and bold playing style helped to greatly increase the popularity of golf. Throughout his career, Palmer has attracted a huge crowd of supporters called "Arnie's Army" at tournaments. His charisma also was largely responsible for making golf a popular television sport.

Arnold Daniel Palmer was born on Sept. 10, 1929, in Latrobe, Pennsylvania. Palmer turned professional after winning the United States Amateur tournament in 1954. He won the U.S. Open in 1960 and the British Open in 1961 and 1962. Palmer joined the Senior PGA Tour in 1980. Palmer's autobiography was published as *A Golfer's Life* (1999). Marino A. Parascenzo

Palmer, Joel (1810-1881), a Canadian-born statesman, won fame as a negotiator of important Indian treaties of 1854 and 1855. As superintendent of Indian affairs for the Oregon Territory from 1853 to 1857, he removed Indian tribes from areas of white settlement. The tribes were upset over losing their lands, but Palmer gave them new areas with generous hunting and farming rights. He was removed from office because many whites believed he was too kind to the Indians. Palmer's *Journal of Travels over the Rocky Mountains* (1847) became a guidebook for travelers. It gives a fine description of a trip on the Oregon Trail. Palmer was born on Oct. 4, 1810, in Ontario. Dan L. Flores

Palmer, Nathaniel Brown (1799-1877), was an American sea captain. He may have been the first explorer to sight Antarctica (see Antarctica [Early exploration]). In 1820, while looking for seal-fishing grounds, he took his sloop, the *Hero,* south from Yankee Harbor in the South Shetland Islands. He sighted the Antarctic Peninsula, an arm of Antarctica extending toward South America. He believed it was only an island. In 1821, he and Captain George Powell, a British sealer, were the first explorers to sight the South Orkney Islands. Palmer was born on Aug. 8, 1799, in Stonington, Connecticut. William Barr

Palmer, Potter (1826-1902), a merchant and real estate promoter, revolutionized the selling methods of his day. Using the "Palmer System," his store in Chicago let customers take home merchandise and inspect it, and make exchanges or get refunds. About 1865, Marshall Field and Levi Z. Leiter became partners in the business. They bought Palmer out two years later. In 1881, the business became Marshall Field and Company. Palmer built the Palmer House, a famous Chicago hotel, and was a leader in developing Chicago's State Street as one of the world's major retail centers. Palmer was born on May 20, 1826, in Albany County, New York. John N. Ingham

Palmerston, *PAH muhr stuhn,* **Viscount** (1784-1865), was a distinguished foreign secretary and prime minister of the United Kingdom. He became secretary of state for foreign affairs in 1830 and, except for a short interval, held the post until 1841. After a five-year absence, he returned to the foreign office in the cabinet of Lord John Russell. He established friendly relations with France, helped Belgium gain independence, and supported Turkey against Russia. Russell dismissed him in 1851. Without consulting his cabinet colleagues or Queen Victoria, Palmerston had approved the seizure of power in France by Napoleon III.

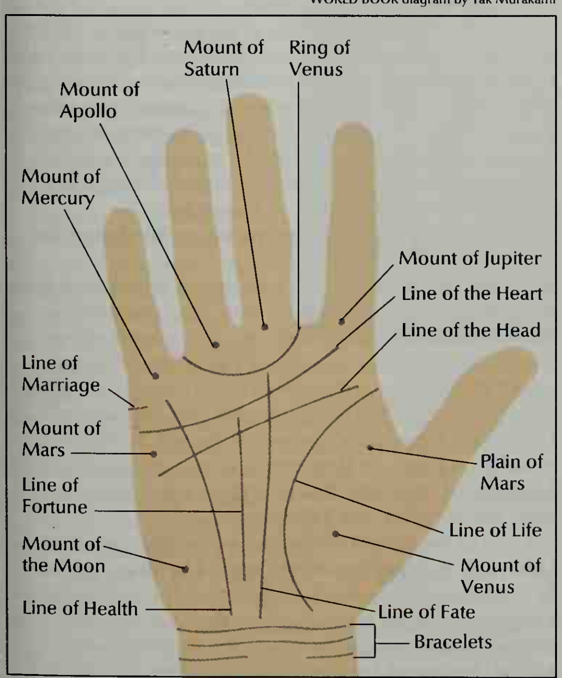
Palmerston's aggressive foreign policy was popular in the United Kingdom, though criticized abroad and in Parliament. He believed in the United Kingdom's greatness in the world and demanded respect for his country from other nations. In one speech, he reminded his lis-

teners that a citizen of ancient Rome was safe anywhere in the Roman Empire, and declared that the United Kingdom would also protect its subjects the world over.

Palmerston became prime minister in 1855. He saw the Crimean War to a successful end but resigned in 1858 because of criticism of his policy in China. He was prime minister again from 1859 until his death.

Palmerston was born on Oct. 20, 1784, at Broadlands, in the county of Hampshire, England. His full name was Henry John Temple. He won election to the House of Commons in 1807, and two years later became secretary at war. He held this office for 19 years. Denis Judd

Palmetto, *pal MEHT oh,* is the name of a group of about 20 species of palm trees. Palmettos grow in Bermuda, the West Indies, Central America, the southeastern part of the United States, and northern South America. They range in height from 6 to 90 feet (1.8 to 27 meters), depending on the species. Palmettos have fan-shaped leaves, which can be used to make baskets, mats, and thatch for huts. The palmetto is the state tree of South Carolina. See also **Cabbage palm; South Carolina** (picture: The state tree). James D. Mauseth



Scientific classification. Palmettos belong to the palm family, Arecaceae or Palmae.

Palmistry, *PAH muh stree,* is the practice of foretelling the future by examining the lines and marks of the human hand. Palmistry, sometimes called *chiromancy,* probably began in ancient India. It was once considered a science. Today, most people regard palmistry as a *pseudoscience* (false science). But people in many parts of the world practice palmistry.

Features of the hand in palmistry

This chart shows the major features of the hand used in reading palms. Palmists study the wrinkles, called *lines,* and the fleshy pads, called *mounts.* These features, palmists claim, can reveal a person's character and foretell his or her future.

WORLD BOOK diagram by Tak Murakami

In palmistry, the fleshy parts of the palm at the base of the thumb and fingers and on the side of the hand are called *mounts.* The mounts are named for Apollo, the god of the sun in Greek and Roman mythology; the moon; and the planets Venus, Jupiter, Saturn, Mercury, and Mars. A well-developed, fleshy mount supposedly means that a person has the characteristics associated with that mount. For example, the mount of Apollo indicates art and riches. Jupiter signifies ambition and pride, and Venus represents love and music.

The wrinkles on the palm are called *lines.* Like the mounts, each line has a name and a meaning. For example, a long line of life supposedly foretells a long life. A long, clear line of the heart indicates an affectionate disposition. A strongly marked line of the head signifies intelligence and imagination.

Many palmists also use various physical and psychological clues in making predictions. Nervousness or small muscular reactions to statements made by the palmist may reveal a person's feelings. The condition of the hands and nails also indicates some characteristics. Such signs may help the palmist make surprisingly accurate predictions. Some palmists use the form of the hand to describe an individual's personality as part of the process of predicting the future. Many of the people who believe in palmistry try to connect it with other occult practices, such as *astrology* (fortunetelling by the stars and planets). Marcello Truzzi

Palmyra, *pal MY ruh,* was an ancient Syrian city, about midway between the eastern coast of the Mediterranean Sea and the Euphrates River. Palmyra was built around an oasis on an important trade route between the Roman and Persian empires. Caravans stopped at Palmyra, bringing great riches and a variety of people and cultures. The temple of Palmyra's chief god, Bel, is typical of the mixture of cultures. Although Bel was an eastern god, the temple's architecture is Roman.

By the A.D. 160's, Palmyra had come under Roman control. Palmyrene camel troops served in the Roman army. Roman troops helped protect Palmyra. However, when Persia invaded Syria about 260, Rome had no troops to spare for Syria's defense. Under Septimius Odenathus, a Palmyrene prince, Palmyrene forces turned back the invading Persians. In 262, Odenathus became Rome's supreme military commander on the eastern frontier. He died in 267, and his widow Zenobia succeeded him.

Zenobia, a vigorous and able ruler, tried to extend her rule over Egypt and all Asia Minor. Her troops seized land from Rome. But the Roman emperor Aurelian captured Zenobia in 274 and destroyed Palmyra. Emperor Diocletian partly restored the city in the late 200's. In the mid-500's, Emperor Justinian used it as a fortress to defend the eastern frontier against Persia. Palmyra fell into decline after Arab forces gained control in 637.

Palmyra palm, *pal MY ruh,* is a kind of palm that grows throughout India and nearby islands and in other hot countries. It is one of the most useful plants known. Lumber from the trunk of the palmyra palm is used for building houses. The leaves are made into thatch, baskets, mats, hats, fans, and umbrellas. The fiber of the

plant is used for twine and rope. The fruit, seeds, and young stalks are eaten. In the northern part of Sri Lanka, the palmyra is almost the sole source of livelihood for thousands of the people.

The ancient Hindu scholars used strips from the leaves of the palmyra and talipot palms for writing material. Some of the oldest existing Hindu manuscripts are preserved in books made of these strips. The books are 1 to 2 feet (30 to 61 centimeters) long and never more than 2 inches (5 centimeters) wide. James D. Mauseth

Scientific classification. Palmyra palms belong to the palm family, Arecaceae or Palmae. Their scientific name is *Borassus flabellifer.*

Palo Alto, *PAL oh AL toh,* California (pop. 58,598), lies between San Francisco Bay and the Santa Cruz Mountains. It is 32 miles (51 kilometers) south of San Francisco and 14 miles (23 kilometers) north of San Jose (see **California** [political map]). Palo Alto means *tall tree* in Spanish. This refers to a tall coastal redwood, a landmark at the northwest entrance to the city.

Palo Alto is one of the nation's leading educational, electronics, medical, and research centers. Stanford University is nearby. The area from Palo Alto southeast to San Jose is called Silicon Valley because of its many computer-related industries. It is so named because silicon is used to make computer chips.

Palo Alto was founded in 1888 and called University Park. In 1892, its name was changed to Palo Alto. The city has a council-manager government. James J. Rawls

Palomar Observatory, *PAL uh mahr,* is an astronomical observatory in southwestern California, about 45 miles (72 kilometers) northeast of downtown San Diego. It stands atop Palomar Mountain, 5,597 feet (1,706 meters) above sea level. The observatory is best known for the Hale telescope, one of the world's largest *optical telescopes.* (An optical telescope collects and focuses visible light given off, or reflected, by celestial objects [see **Telescope**].) The Hale telescope was named for American astronomer George Ellery Hale, who planned its construction (see **Hale, George Ellery**).

In 1963, astronomers using the Hale telescope first identified *quasars,* extremely bright objects in the center of some distant galaxies (see **Quasar**). Energy from quasars takes billions of years to reach the earth. For this reason, the study of quasars can provide information about early stages of the universe.

The Hale telescope is a *reflecting telescope* (one that collects and focuses light with a concave mirror). Its mirror is 200 inches (508 centimeters) in diameter. This telescope can also be equipped with detectors for observation and photography with *infrared rays* (heat rays). One major use of these detectors is the study of stars in the process of formation. Palomar also has a reflecting telescope with a 60-inch (152-centimeter) mirror.

In addition, the observatory has two *Schmidt telescopes.* These telescopes are instruments with both a large mirror and a large lens. The bigger of the two telescopes, called the Oschin telescope, has a 72-inch (183-centimeter) mirror and a 48-inch (122-centimeter) lens. This telescope, built to map the sky and locate celestial bodies for detailed study with the Hale telescope, can photograph an area of the sky about 200 times as large as the area that the Hale telescope can map. However, the Hale telescope provides images with greater detail.

During the 1950's, astronomers used the Oschin telescope to map millions of stars and galaxies. This survey revealed the distant sources of light that later were discovered to be quasars. In 1982, astronomers began to repeat this survey, using more sensitive photographic plates. The Palomar Observatory began operations in 1948. It is owned by the California Institute of Technology. Paloverde, *PAH loh VAIR day,* is the name of two species of thorny trees that grow in the dry regions of the Southwestern United States. Paloverdes grow along the sides of desert canyons and dry stream beds in southern and central Arizona, southeastern California, and northwestern Mexico. Both species—the *blue paloverde* and the *foothill paloverde*—represent the state tree of Arizona.

A paloverde grows from 15 to 30 feet (4.6 to 9 meters) tall and its trunk may be up to 20 inches (51 centimeters) in diameter. It has green bark and leaves about 1 inch (2.5 centimeters) long that unfold in late March or April. The leaves fall almost as soon as they are full grown, and the tree is usually bare by late summer. In late April and May, paloverdes bear small yellow flowers.

A paloverde produces seed pods 2 to 3 inches (5 to 8 centimeters) long. Each pod usually contains two to four large seeds. Indians once dried the seeds and ground them into meal, or ate immature seeds raw. Paloverdes have little commercial value. But the roots help hold loose desert soil together and slow *erosion* (wearing away) of the soil. Donald J. Pinkava

Scientific classification. Paloverdes belong to the pea family, Fabaceae or Leguminosae. The scientific name for the blue paloverde is *Cercidium floridum.* The foothill paloverde is *C. microphyllum.*

Palsy, *PAWL zee,* means the same as *paralysis,* the loss of movement or sensation (see **Paralysis**). The term *palsy* is most commonly used in connection with certain types of paralysis. Some kinds of palsy are caused by continued pressure on a nerve. Shaking palsy *(paralysis agitans),* an involuntary tremor of the muscles, is another name for Parkinson disease. *Chemopallidectomy* is an operation for this tremor. Daniel S. Barth

Pamirs, *pah MEERZ,* is a huge region where the Himalaya, Hindu Kush, Kunlun, and Tian Shan mountains meet. It is one of the highest mountain ranges of the world. The region is sometimes called *Bam i Dunya,* which means *roof of the world.* It lies mostly in Tajikistan, but parts of the region extend into Afghanistan, China, and Kyrgyzstan. The region covers 36,000 square miles (93,200 square kilometers), at an average height of 13,000 to 15,000 feet (3,960 to 4,570 meters) above sea level. For location, see **Tajikistan** (map).

Most of the Pamirs is treeless, with either grass or bare rock. Rugged mountains are cut by deep canyons. In summer, native people find pasture for their cattle on the gentler slopes along the few lakes and the *Amu Darya* (Oxus River). Snow covers the mountains and blocks the passes for more than half of each year. High

winds blow across the mountains during the summer months. James A. Hafner

Pampa, *PAM puh,* is a Spanish word that means *plain.* Geographers use the word *pampa* for several great plains of South America. But it is most commonly used for the huge plain in Argentina that fans out around Buenos Aires. An area of fertile soil and much grassland, the Argentine Pampa yields abundant crops and supports livestock. It is also the site of most of Argentina's urban areas. More than two-thirds of Argentina's people live on the Pampa. See also **Argentina** (terrain map; The Pampa; Agriculture). Jerry R. Williams

Pamphlet is a short published work of topical interest through which the writer wishes to inform or persuade the public. A pamphlet is usually bound in paper covers. Pamphlets originally consisted of manuscripts bound in covers. The word *pamphlet* comes from *Pamphilius, seu de Amore,* a Latin poem published in this form in the 1100's. Most early pamphlets discussed religious questions. Political issues formed the subject matter of pamphlets during the 1600's and 1700's. Charles F. Sieger

Pan was the god of woods and pastures in Greek mythology. He also was the protector of shepherds and their flocks. Shepherds and farmers prayed to Pan to make their animals fertile.

Pan was half man and half goat. The ancient Greeks believed he had a wild, unpredictable nature. They also thought he had the power to fill human beings and animals with sudden, unreasoning terror. The word *panic* comes from his name.

The Greeks associated Pan with wilderness regions. They believed he lived in caves, on mountain slopes, and in other lonely places. The worship of Pan began in Arcadia, a remote region of southern Greece. Pan's father, Hermes, also was associated with Arcadia. The worship of Pan spread until he became one of the most popular gods.

Marble sculpture (A.D. 1-99); National Museum of Athens (Art Resource)

The Greek god Pan was half man and half goat. He had many love affairs with divinities. In this sculpture, he is with Aphrodite, *left,* and Eros, *center,* the goddess and god of love.

Pan had many love affairs with nymphs and other divinities (see **Nymph**). He tried to start an affair with the nymph Syrinx, but she ran away from him in terror and begged the gods to help her. The gods changed Syrinx into a bed of reeds, from which Pan made a musical instrument called a *panpipe.* He became famous for the beautiful music he played on the panpipe. C. Scott Littleton

Pan-American conferences have brought together representatives from countries of North, Central, and South America. These meetings also have been called *Inter-American conferences.* Through them, the nations have worked to create closer and more friendly economic, cultural, and political relations with one another.

The original Pan-Americanism. Simón Bolívar, a South American statesman, took the first steps toward setting up an arrangement among American republics (see **Bolívar, Simón**). Through his efforts, various independent American countries held their first conference in 1826 in Panama City, Panama. Other conferences took place in Lima, Peru, in 1847; in Santiago, Chile, in 1856; and in Lima in 1864. These meetings attracted delegates from Spanish American republics and focused on political issues, such as cooperation among the countries in the defense of their national sovereignty.

The "new" Pan Americanism. By 1889, the United States had begun to exercise leadership in inter-American affairs. That year, U.S. interest in expanding trade with Latin America led to the First International Conference of American States, also known as the *Pan-American Conference,* in Washington, D.C. The conference established the International Union of American Republics, with the Commercial Bureau of the American Republics as its central office. In 1910, the bureau became the Pan American Union. The five conferences between 1889 and 1933 met under a cloud of fear of the United States. During this time, the United States interfered in the affairs of several Latin American countries, often by force.

"Good Neighbor" Policy. United States President Herbert Hoover realized the need for better relations between the United States and Latin American countries. However, significant progress toward that goal occurred only after Hoover's successor, Franklin D. Roosevelt, established the Good Neighbor Policy. This policy affirmed that no nation had a right to interfere in the affairs of another nation. The United States endorsed the policy at conferences in Montevideo, Uruguay, in 1933 and in Buenos Aires, Argentina, in 1936. The Good Neighbor Policy led to increased cooperation between the United States and Latin American countries during World War II (1939-1945).

Stronger ties. Representatives at a Mexico City meeting in 1945 sought to further strengthen the Inter-American system. The first step in this direction was a treaty to meet acts of aggression. In a 1947 conference held near Rio de Janeiro, representatives drew up the Inter-American Treaty of Reciprocal Assistance, or *Rio Treaty,* which declared that an armed attack on one member was an attack against all.

An Inter-American Conference held at Bogota in 1948 resulted in the establishment of the Organization of American States (OAS). The Pan American Union became the permanent body of the OAS and eventually was named the organization's General Secretariat.

After 1948, Cold War issues often dominated the Inter-American conferences. These issues included ways to achieve political reform and economic growth in the Western Hemisphere to help stop the spread of Communism. In 1960, the OAS took its first collective action against a country. It imposed diplomatic sanctions against the Dominican Republic, then under the control of dictator Rafael Trujillo.

In 1961, the United States and Latin American countries established the Alliance for Progress. This pro-

gram, proposed by U.S. President John F. Kennedy, called for social and economic development based on democracy and capitalism. But the program failed to end Communist rule in Cuba or the Communist movements in some other Latin American countries. Communists had gained power in Cuba in 1959.

In 1962, the OAS unanimously supported a United States naval quarantine aimed at preventing Soviet nuclear weapons from entering Cuba. In 1969, an OAS conference of foreign ministers acted quickly to end an invasion of Honduras by troops from El Salvador.

Amendments to the OAS charter went into effect in 1970. They provided for a General Assembly that would meet annually. The General Assembly replaced the Inter-American Conference, which had usually held regular sessions every five years. Since the late 1970's, the OAS has struggled to reduce revolutionary and other political turmoil in Central America. But it has had little effect. Mark T. Gilderhus

Pan American Games are a series of athletic contests patterned after the Olympic Games and sponsored by the Pan American Sports Organization (PASO). PASO is made up of Western Hemisphere nations. The games are held once every four years, usually the year before the summer Olympic Games. For more information, see **Olympic Games.**

The Pan American Games were inaugurated after World War II by the Pan American Sports Congress, which became PASO in 1967, as a way to increase good will among the countries of the Americas. The first Pan American Games were held in Buenos Aires, Argentina, in 1951. Dave Nightingale

Pan American Highway is a system of highways that extends from the United States-Mexican border to southern Chile. It also connects the east and west coasts of South America, and links the capitals of 17 Latin American countries. The 29,525-mile (47,516-kilometer) system benefits Latin America's economy. It provides a route for raw materials and agricultural products through much of Latin America. The Pan American Highway is sometimes described as running through the western United States and Canada up into Alaska. But neither country has officially named any highway as part of the Pan American Highway system.

Route. The Pan American Highway has four major U.S. terminals: Nogales, Arizona; and Eagle Pass, El Paso, and Laredo, Texas. It crosses Mexico, Guatemala, El Salvador, Honduras, Nicaragua, and Costa Rica, and into Panama. The Darien Gap, a stretch of about 70 miles (110 kilometers) of jungle, blocks the highway at Yaviza, Panama. Motorists usually ship their cars from either Cristobal or Balboa, Panama, to Colombia or Venezuela. South of the gap, the highway follows the western coastline of South America to Puerto Montt, Chile.

At Santiago, Chile, about 660 miles (1,060 kilometers) north of Puerto Montt, a major branch of the highway cuts eastward across the Andes Mountains to Buenos Aires, Argentina. It then follows the east coast of South America north to Rio de Janeiro, Brazil, where it turns inland to Brasilia, the capital of Brazil. Other branches of the highway lead to the capitals of Bolivia (La Paz and Sucre), Paraguay (Asunción), and Venezuela (Caracas).

WORLD BOOK map

The Pan American Highway provides a route through much of Latin America for raw materials and agricultural products.

Development. The idea to link North and South America dates from the late 1800's, when people talked of building a Pan American railway. But it was not until 1923, at the Fifth International Conference of American States, that a highway was seriously considered. This conference led to the First Pan American Highway Congress at Buenos Aires in 1925.

Organization of the system started in the late 1920's. By 1940, over 60 percent of the highway between the United States and Panama had been completed. By the early 1950's, most of the project was open to travel in South America. An important link in the system opened in 1962, when the Thatcher Ferry Bridge was completed over the Panama Canal at Balboa. The bridge is 1 mile (1.6 kilometers) long and is one of the world's longest steel arch bridges.

Each South American country has financed the building of the highways within its own borders. In 1930, the United States began giving financial support to speed the building of the Pan American Highway between Panama and Texas. This section is also called the Inter-American Highway. The United States has contributed two-thirds of the cost of building this part of the highway. Only Mexico has not used United States financial aid in building the system.

The Pan American Highway Congress, sponsored by the Organization of American States (OAS), meets every four years to discuss the development and progress of the highway system. The congress has headquarters in the General Secretariat of the OAS in Washington, D.C.

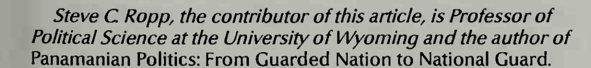
Panama

Panama is a small country in Central America that has worldwide importance as a transportation center. It covers the Isthmus of Panama, a narrow strip of land that separates the Atlantic and Pacific oceans near the middle of the Western Hemisphere. The Panama Canal cuts through the isthmus, connecting the two oceans. Thousands of ships use the canal each year to pass from one ocean to the other. By doing so, they avoid a long trip around the southern tip of South America. Thus, Panama plays a key role in the world's transportation system. The country is sometimes called the *Crossroads of the World* because of this role.

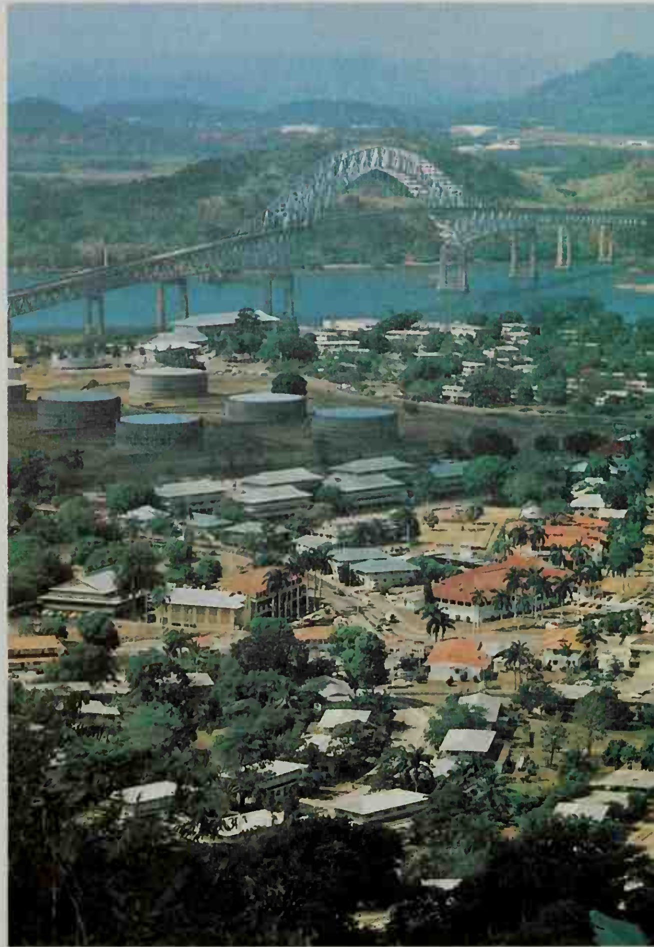
Panama lies at the southern end of North America. It and the land north of it to Mexico's southern border make up the part of the North American continent called Central America. Panama is a narrow country that curves from west to east. The Atlantic Ocean lies to the north, the Pacific Ocean to the south, Colombia to the east, and Costa Rica to the west.

Lowlands cover the part of Panama near the Atlantic and Pacific coasts. The Atlantic coast is sometimes referred to as the Caribbean coast because it borders the part of the Atlantic Ocean that is called the Caribbean Sea. Mountains cover much of Panama's interior, and there are jungles and swamps in the east. Panama City is the country's capital and largest city.



Mestizos (people of mixed American Indian and white ancestry) and *mulattoes* (people of mixed black and white ancestry) make up more than two-thirds of Panama's population. Most of the rest of the people are of unmixed American Indian, black, or white ancestry.

Indians were the first inhabitants of what is now Panama. Spaniards conquered the Indians during the 1500's and ruled Panama for about 300 years. In 1821, Panama broke away from Spain and became a province of the nation of Colombia. In 1903, it rebelled against Colombia and became an independent nation.



The United States played a major role in Panama's history. It built the Panama Canal, which was completed in 1914. Many U.S. civilians and soldiers then moved to Panama to guard, operate, and maintain the canal. They lived in a special area bordering the canal called the Panama Canal Zone. The United States took control of the canal and the zone in exchange for payments to Panama. In 1977, Panama and the United States signed a treaty that resulted in the transfer of the Canal Zone to Panama in 1979. Also as a result of the treaty, the United States transferred control of the canal to Panama on Dec. 31, 1999. For details on the canal and the Canal Zone, see **Panama Canal; Panama Canal Zone**.

Government

According to its Constitution, Panama is a republic. The Constitution grants the people such rights as freedom of speech and religion. Panamanians 18 years of age or older may vote in elections.

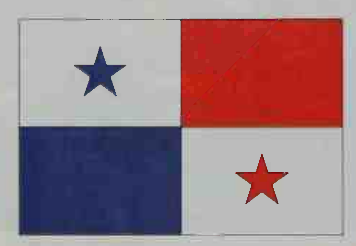
Panama is famous as the site of the Panama Canal, one of the world's most important waterways. Thatcher Ferry Bridge, *shown here,* crosses the canal near Panama City, the country's capital.

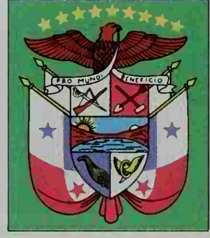
Facts in brief

Capital: Panama City.
Official language: Spanish.
Official name: *República de Panamá* (Republic of Panama).
Area: 29,157 mi² (75,517 km²). *Greatest distances*—east-west, 410 mi (660 km); north-south, 130 mi (209 km). *Coastline*—Atlantic Ocean, 397 mi (639 km); Pacific Ocean, 746 mi (1,201 km).
Elevation: *Highest*—Volcán Barú, 11,401 ft (3,475 m) above sea level. *Lowest*—sea level along the coasts.
Population: *Estimated 2002 population*—2,938,000; density, 101 per mi² (39 per km²); distribution, 56 percent urban, 44 percent rural. *1990 census*—2,329,329.
Chief products: *Agriculture*—bananas, rice, sugar cane, beef cattle, milk, coffee, corn, chickens and eggs, beans. *Manufacturing*—beverages, cement, petroleum products, processed foods. *Fishing*—shrimp, anchovetta.
National anthem: "Himno Nacional de la República de Panamá" ("National Hymn of the Republic of Panama").
Money: *Basic unit*—balboa. One hundred centésimos equal one balboa.



National government of Panama is headed by a president. The president is elected to a five-year term by the people. A Cabinet assists the president in carrying out the day-to-day operations of the government. The National Assembly makes the country's laws. The people elect the members of the National Assembly to five-year terms.

Local government. Panama is divided into nine provinces for the purposes of local government. The provinces are subdivided into municipal districts. The president appoints a governor to head each province. The people elect mayors and councils to govern Panama's districts. Local government officials in Panama have little policymaking authority. In general, these officials simply carry out policies made by the national government.



Politics. Panama has a number of political parties. The major parties include the Arnulfista Party, the Democratic Revolutionary Party, and the Papa Egoro Party.

Courts. The Supreme Court is Panama's highest court. It hears appeals from lower courts. It has nine members, who are appointed by the president to 10-year terms. Panama's lower courts include superior, circuit, and municipal courts.

Armed forces. Panama has no regular armed forces. Security is provided by the Public Forces. These civilian forces are the National Police, the National Air Service, and the National Maritime Service. Together they have about 12,000 members. Service is voluntary.

Panama's flag was adopted in 1903. Its blue star stands for honesty and purity. The flag's red star symbolizes authority and law.

The country's coat of arms bears Latin words meaning *For the Benefit of the World.* This motto refers to the role of the Panama Canal.

WORLD BOOK map

Panama occupies a narrow strip of land between the Pacific Ocean and the Caribbean Sea, a part of the Atlantic Ocean.

Michele and Tom Grimm

People

Population and ancestry. A little more than half of Panama's people live in urban areas, and the rest live in rural areas. Panama's largest cities are—in order of population—Panama City, San Miguelito, and Colón. Together, these three cities have about three-fourths of the nation's urban population.

Panama has a mixed population. American Indians were its first inhabitants. In the 1500's, Spaniards became the first whites to reach Panama. They brought black slaves from Africa to Panama. In the 1800's, many blacks of African descent who were living in the West Indies settled in Panama.

Through the years, Indians, whites, and blacks intermarried. Today, about two-thirds of Panama's people are descendants of more than one group. The largest mixed groups are mestizos and mulattoes. Together, they make up about 70 percent of the population. Blacks and whites each make up from 10 to 15 percent, and Indians about 6 percent.

Way of life. The part of Panama near the Panama Canal is a busy center of urban activity. In contrast, most of the rest of the country is made up of quiet rural areas of farms, tiny villages, and small towns.

Panama City lies at the Pacific end of the Panama Canal, and Colón is at the Atlantic end. These cities are active centers of commerce, trade, and transportation. They have many modern, high-rise office buildings, and hotels, nightclubs, bars, and gambling establishments. The cities' main streets are crowded with foreign traders, sailors, and tourists, as well as Panamanians. The Panama Canal and the 10-mile (16-kilometer)-wide area that was formerly the Panama Canal Zone lie between Panama City and Colón. Through the years, people from the United States, called Zonians, established communities that resemble United States towns and suburbs in this area. The communities include Balboa and Cristóbal.

Most of Panama's white people live in the area near

the Panama Canal. Many of the whites are extremely wealthy. A small group of Panama's people, most of them wealthy whites, are called the *elite*. Their families have had wealth for several generations. The elite take great pride in their traditions, and they tend to avoid social contact with other Panamanians. This group includes bankers, industrialists, large commercial farmers, and important doctors and lawyers.

Many other whites and also many mestizos and mulattoes of the Panama Canal area belong to the middle class. They include merchants, government officials, and office workers. Most of Panama's black people live near the canal. Large numbers of the blacks are poor laborers. As in many other countries, the blacks suffer from discrimination in job opportunities.

Most Panamanians who live away from the Panama Canal area are farmers. Mestizos and mulattoes form the majority of the country's farm population. They make their homes in small villages or on farm fields, primarily in western Panama. Many of the country's farmers struggle to produce enough food for their own use.

Most of Panama's Indians live in rural areas. The main Indian groups are the Chocó, Cuna, and Guaymí. Cuna Indians who live on the San Blas Islands off Panama's northern coast are sometimes called San Blas Indians. Panama's Indians farm and fish for a living.

Traditionally, Panamanian women have had little opportunity for higher education or careers. They have been expected to marry early, raise large families, and manage their household. But since the mid-1900's, more and more women have taken jobs outside the home.

Housing. Wealthy Panamanians live in large houses built in either the Spanish colonial or a modern architectural style, or in large luxury apartments. Most middle-class people have smaller houses or apartments. Panama's poor urban people live in shacks or run-down apartments. Most rural people live in small one- or two-room houses. Many houses near the Pacific coast have

A street scene in Colón shows people of various ethnic backgrounds. Most Panamanians are of mixed Indian and white, or black and white, descent.

Traditional costumes are worn by many Panamanians on special occasions. The woman above wears a colorful *pollera* while dancing at a fiesta. The man's shirt is called a *camisilla.*

thatched roofs, and walls made from sugar cane stalks. Many houses near the Atlantic coast are made of wood.

Clothing. Most Panamanians wear Western-style clothing most of the time. On holidays and other special occasions, large numbers of people dress in special costumes. Women may wear a *pollera,* a white garment consisting of a blouse and long full skirt that are decorated with lace and embroidery. Or, they may wear a costume of a white blouse and brightly colored skirt called a *montuna.* Men may wear a *montuno,* which consists of a white embroidered shirt and short trousers. A *camisilla* (long, white shirt) and long trousers is another special costume worn by men.

Many Panamanian farmers wear straw hats while working. These hats, which are made in Panama, are sometimes mistakenly called *Panama hats.* But Panama hats are made in Ecuador, and are not worn by many Panamanians. They received the name Panama hats during the 1800's, when Panama became a center for the shipment of the hats to other countries.

Panama's Indians, especially women of the San Blas group, are famous for their colorful costumes. San Blas women wear brightly colored garments that have elaborate embroideries. They also wear a ring that hangs from the nose and large metal disks for earrings.

Food and drink. Rice is the basic food of most Panamanians. Many of the people cook rice with beans to make a dish called *guacho. Tortillas* (flat breads made from corn or wheat flour) are a favorite food. Coffee and beer are popular beverages among Panamanians.

Recreation. Music is a favorite form of recreation in Panama. Most Panamanians enjoy musical performances, and many play instruments for recreation. Celebrations called *fiestas* are held on holidays. Fiestas feature religious rituals, dancing, music, and special meals. Baseball is the most popular sport in Panama, and basketball is also popular. Panamanians learned about these sports from U.S. citizens who moved to the country after the canal opened. Soccer is also popular.

Languages. Spanish, Panama's official language, is spoken by nearly all the people. Some Indian groups use their own local language in addition to Spanish. Many Panamanians can speak English.

Religion. About 85 percent of Panama's people are Roman Catholics. Most of the rest of the people are Protestants. The Catholic Church plays an important role in Panama. Church services and celebrations are both religious and social events for many of the people.

Education. Most of Panama's adults can read and write. For the country's literacy rate, see **Literacy** (table: Literacy rates). Panamanian law requires children to attend school from the ages of 6 to 15, or until they complete the sixth grade. But about half the children leave school before completing the requirement. Most are from poor families and leave school to begin work. About half the students who complete the sixth grade also complete high school. Panama has two universities, both in Panama City. They are the University of Panama and the University of Santa María la Antigua.

Land and climate

Panama covers the Isthmus of Panama, which has an area of 29,762 square miles (77,082 square kilometers). The isthmus extends about 410 miles (660 kilometers)

from west to east. From north to south, it measures only about 130 miles (209 kilometers) at its widest point and 30 miles (48 kilometers) at its narrowest point.

The Panama Canal cuts through the center of the country, dividing the land into eastern and western sections. Approximately 98 percent of the people live near the canal or in the part of the country west of it. Swamps and jungles cover much of Panama east of the canal. Only about 2 percent of the people, chiefly Indians, live in the east.

Many wild animals live in Panama. They include jaguars, ocelots, pumas, monkeys, and parrots and other tropical birds. Pine trees are abundant in Panama's mountains. Banana plants and cacao trees are grown in many parts of the country.

Panama has three land regions—the Central Highland and coastal lowlands called the Atlantic Lowland and the Pacific Lowland.

The Central Highland is a mountainous region. The Tabasará Mountains extend eastward from the Costa Rican border. The country's highest peak, 11,401-foot (3,475-meter) Volcán Barú rises near the border. The mountain range decreases in height as it extends eastward. It is made up of low hills near the Panama Canal. Panama's land rises to mountains again east of the canal. The San Blas Mountains and Darién Mountains, the main ranges in the eastern part of the country, reach heights of about 6,000 feet (1,800 meters). Valleys between the mountains in western Panama provide much good farmland.

The coastal lowlands are narrow areas that lie along Panama's Pacific and Atlantic coasts. The Pacific Lowland has much fertile farmland, which is located chiefly in the west. The Atlantic Lowland is less fertile.

Coastline and islands. Panama's Pacific coastline measures 746 miles (1,201 kilometers). The Atlantic coastline is 397 miles (639 kilometers) long. About 800 islands that lie near the coasts are part of Panama's territory. The largest ones are Coiba Island and Rey Island, both off the Pacific coast.

Rivers and lakes. Panama has about 500 rivers. But only one river, the Tuira, is navigable for long distances. The Tuira flows for 125 miles (201 kilometers) in eastern Panama. Panama has no large natural lakes. Its largest lake is the 163-square-mile (422-square-kilometer) Gatun Lake, which was created by the builders of the Panama Canal and forms part of the canal route.

WORLD BOOK photo by Terry K. McClellan

The Central Highland, shown here, is a region that covers much of Panama inland from the Atlantic and Pacific coasts. The areas near the coasts are flatter than the rugged highland.

Climate. Most of Panama has a warm, tropical climate that varies little from season to season. Temperatures in the lowlands average about 80° F. (27° C). Mountain temperatures average about 66° F. (19° C). The Atlantic side of Panama receives about 150 inches (381 centimeters) of rain annually. About 68 inches (173 centimeters) of rain falls in the Pacific side yearly.

Economy

Economic activity in Panama varies according to location. Near the Panama Canal, the economy is based on business generated by the waterway, and on commerce, trade, manufacturing, and transportation. In most of the rest of Panama, the economy is based on agriculture. The economy of Panama operates as a free enterprise system.

The Panama Canal is the most important single factor in the country's economy. Tolls from ships that pass through the canal contribute millions of dollars annually to the Panamanian economy. The Panama Canal also directly and indirectly provides jobs for many Panamanians. The jobs include positions related to the operation and maintenance of the canal. They also include jobs in stores and other businesses that exist because of the economic activity generated by the canal.

Commerce and trade flourish near the Panama Canal. Colón and Panama City rank among Latin America's chief banking centers. Colón has a Free Trade Zone, where merchants can import and export goods without paying *duties* (taxes). Many merchants send goods to Colón and then export them to other nations to save money. More than 300 import and export companies operate in the Free Trade Zone.

Manufacturing. About two-thirds of Panama's manufacturing firms are located in Panamá Province, just west of the canal. The country has few large manufacturing industries. Its chief products include beer, cement, and cigarettes. Panama has many plants that process food, including fish, fruit, milk, and sugar. An oil refinery located near Colón processes crude oil from other countries into petroleum products.

Agriculture employs about a fourth of Panama's workers—more people than does any other single economic activity. Most of these workers farm a small plot of land and use old-fashioned agricultural equipment and methods. The majority of the farmers produce only *subsistence crops*—that is, crops raised by farmers for their own use. Rice is the main subsistence crop, followed by corn and beans. Bananas rank as the chief *cash crop.* Cash crops are those that are raised for sale. Other cash crops grown in Panama include sugar cane, coffee, and tobacco. Cattle ranching is another important agricultural activity. Panamanian farmers also raise chickens and hogs.

Most Panamanians who raise subsistence crops own or rent their farms. But many of them are *squatters.* Squatters neither own nor rent the land they farm. Instead, they simply settle on land owned by the government or private citizens and farm it. Most of Panama's cash crop production takes place on large farms owned by wealthy landowners. The landowners hire agricultural workers to farm their land.

Fishing. Shrimp is the most important product of Panama's fishing industry. Anchovetta, a small fish that is ground into fish meal, ranks second. Other catches include herring and lobster.

Mining. Panama's small mining industry centers around the production of such construction materials as lime, sand, and crushed stone. Large copper deposits lie near Colón and David. However, these deposits are undeveloped.

International trade. Bananas, shrimp, and sugar are Panama's chief exports. Imports include automobiles, chemicals, machinery, and petroleum. The United States is Panama's chief trading partner. Panama also carries on much trade with Japan, Venezuela, and several Western European countries.

Transportation and communication. Panama is a major center of international transportation by sea and air. About 13,000 ships pass through the Panama Canal yearly. Cristóbal, a suburb of Colón; and Balboa, a suburb of Panama City, are busy international ports. The main airport is at Tocumen, near Panama City.

Panama's merchant marine is the largest in the world. Shipping lines of other countries own most of the ships. These companies register the ships in Panama because Panama allows them to pay lower taxes and wages than do their own countries, and also in order to avoid some safety regulations.

Only about a third of Panama's road system is paved. Most rural roads in Panama have a dirt surface. The country's major road is the Panamanian section of the Pan American Highway. It runs from the Costa Rican border to the eastern part of the country. Another important road in Panama is Trans-Isthmian Highway between Colón and Panama City.

Panama has six daily newspapers. The country has an average of about 1 radio for every 5 people and about 1 television set for every 7 people.

History

Early days. Indians were the first inhabitants of what is now Panama. Few early records of the Indians exist, and scholars have not determined when the Indians first settled in the region. The Indians farmed, fished, and hunted.

Yoram Kahana, Peter Arnold, Inc.

A farmer and his son carry home sugar cane and coconuts they have gathered. Agriculture employs more Panamanians than does any other activity. Most farming is on a small scale.

The Spanish colonial period. Spain took control of what is now Panama from the Indians during the early 1500's. In 1501, Rodrigo de Bastidas, a Spanish explorer, became the first white person to reach the area. In 1502—during his fourth voyage to the New World—Christopher Columbus, an Italian navigator employed by Spain, landed in what is now Panama. He claimed the area for Spain. A group of Spanish soldiers and colonists reached Panama in 1510. The Spaniards established colonies along the Atlantic coast. The Indians told the Spaniards of a large body of water that lay across the Isthmus of Panama, not far away. The body of water was actually the Pacific Ocean. Vasco Núñez de Balboa, acting governor of the colonies, led an expedition across the isthmus. On Sept. 25, 1513, he became the first white person to see the eastern shore of the Pacific.

The fact that Panama was only a narrow strip of land between the Atlantic and Pacific made the area important to the Spaniards. Sailing from military bases they established along the Panamanian Pacific coast, the Spaniards explored the west coast of Latin America. They conquered many of the Indian lands they reached. The most important conquest took place in the 1530's, when Spaniards led by Francisco Pizarro defeated the Inca of Peru. They took gold and other riches from the Inca and from other Indians. Spain built a stone road across Panama to transport the riches from the Pacific to the Atlantic coast. The riches then were shipped to Spain.

The Spaniards did little to develop Panama's economy. They treated the Indians harshly and killed many of them. Under Spanish rule, Panama became a center for the distribution of black African slaves in the New World.

In the 1600's, Henry Morgan of England and other pirates attacked Spanish ships and towns in Panama. Many Spanish ships carrying goods from Peru began sailing around the tip of South America to avoid the pirates. Panama declined as a transportation center.

Colombian rule. Colombia gained independence from Spain in 1819. In 1821, Panama broke away from Spanish rule and became a province of Colombia.

A gold rush began in California in 1848. People from the Eastern United States began sailing to Panama, crossing the isthmus to the Pacific, and then sailing on to California to reach the gold rush area.

Businessmen from the United States built a railroad across Panama to speed up passage across the isthmus. The railroad was completed in 1855, and Panama again became a busy transportation center.

Many laborers from other lands moved to Panama to help build the railroad. They included thousands of blacks from the West Indies. Many of the black laborers settled permanently in Panama.

Relations between Panama and the rest of Colombia were always strained, and, beginning in 1830, Panamanians staged several revolts against Colombia. In 1903, Colombia refused an offer by the United States to build a canal across Panama. Panama, encouraged by the United States, then revolted against Colombia. It became an independent nation on Nov. 3, 1903. The United States hoped to gain approval to build the canal from the newly independent country. It sent ships and troops to protect the new government against an overthrow by

Colombia. The United States, with Panama's approval, then began building the canal.

Progress as a nation. The Panama Canal was opened on Aug. 15, 1914. It brought prosperity to the part of Panama near the waterway. The United States established the former Panama Canal Zone there. The economies of the Canal Zone, Colón, and Panama City flourished. Many Panamanians moved to the canal area to find jobs. But the changes near the canal had little effect on other parts of Panama. Most of the country remained rural and underdeveloped.

Political rivalries brought instability to Panama's government during the early and mid-1900's. The government changed hands many times.

Relations with the United States. Many Panamanians opposed United States control of the Panama Canal and Canal Zone. They demanded Panamanian control. In the 1950's and 1960's, Panamanians staged many demonstrations and some riots against the continued U.S. presence.

In 1968, Omar Torrijos Herrera, a military officer, took over the government of Panama and began to rule as a dictator. He strengthened the movement to end U.S. control of the canal and Canal Zone. In 1977, Panama and the United States signed a treaty designed to end U.S. control. The treaty resulted in the transfer of the Canal Zone to Panama in 1979. It also provided for the transfer of the canal itself to Panama in 1999.

The Noriega years. General Torrijos gave up control of Panama's government in 1978. Civilian leaders took over, but Torrijos kept much power as head of the military. Torrijos died in a plane crash in 1981. The military continued to hold much power in Panama after his death.

In 1983, General Manuel Antonio Noriega became head of the military and Panama's most powerful leader. In 1987, a former aide of Noriega accused him of fraud in the 1984 presidential election, killing a political opponent, and making large amounts of money through corruption. In 1988, two U.S. federal grand juries in Florida indicted Noriega on charges of drug trafficking and racketeering in the United States. Panamanian President Eric Arturo Delvalle dismissed Noriega from his military command, but Noriega supporters forced the president from office. The U.S. government denounced this action. It imposed extreme economic sanctions against Panama and called for Noriega's resignation.

In 1989, Panama held a presidential election. Guillermo Endara, a politician opposed to Noriega, apparently won the election. But the Panamanian government declared the election invalid. On Oct. 3, 1989, a group of Panamanian soldiers tried to overthrow Noriega, but failed. The United States provided minor aid to the rebels by blocking some key roads. In December 1989, Panamanian soldiers killed a United States marine lieutenant. Mentioning this incident and the drug trafficking charges, U.S. President George H. W. Bush ordered troops into Panama to overthrow Noriega.

In January 1990, Noriega surrendered to United States officials, and Endara was named president of Panama. A new civilian government was formed. In 1992, Noriega was convicted on charges of drug trafficking, money laundering, and racketeering.

Recent developments. In 1994, Ernesto Pérez Balladares was elected to succeed Endara as president. In 1999, Mireya Moscoso became the first woman to be elected president of Panama. Also that year, on December 31, the United States handed over control of the Panama Canal to Panama.

Today, Panama faces some major changes and challenges, mainly as a result of the transfer of the Panama Canal from U.S. to Panamanian control. Although the United States still has some influence over the protection of the canal, Panama is entirely responsible for its maintenance and for protection of the surrounding rain forests. These forests provide the water that is used in the canal locks to lift and lower ships. They are increasingly threatened by poor people looking for new places to grow their food.

Panama also faces some major challenges that are not directly related to the canal. Many Panamanians live in poverty, and rich people are consuming an increasing share of the country's wealth. The government will need to find ways of dealing with the problem of poverty and ensuring that the country's economy continues to grow.

The Panama Canal is an artificial waterway that cuts across Central America and links the Atlantic and Pacific oceans. The canal enables ships to travel between Atlantic and Pacific ports without sailing around South America, saving a distance of more than 7,800 miles (12,600 kilometers).

Panama Canal is a waterway that cuts across the Isthmus of Panama and links the Atlantic Ocean and the Pacific Ocean. It ranks as one of the greatest engineering achievements in the world. Upon its completion in 1914, the canal shortened a ship's voyage between New York City and San Francisco to less than 5,200 miles (8,370 kilometers). Previously, ships making this trip had to travel around South America—a distance of more than 13,000 miles (20,900 kilometers).

The United States built the Panama Canal at a cost of about $380 million. Thousands of laborers worked on it for about 10 years, using steam shovels and dredges to cut through jungles, hills, and swamps. They had to conquer such tropical diseases as malaria and yellow fever.

The Panama Canal extends about 51 miles (82 kilometers) from Limón Bay on the Atlantic Ocean to the Bay of Panama on the Pacific Ocean (see **Panama** [map]). A ship traveling through the canal from the Atlantic to the Pacific sails from northwest to southeast. The ship actually leaves the canal 27 miles (43 kilometers) east of where it entered.

The canal has three sets of water-filled chambers called *locks,* which raise and lower ships from one level to another. The locks were built in pairs to allow ships to pass through in both directions at the same time. Each lock has a usable length of 1,000 feet (300 meters), a width of 110 feet (34 meters), and a depth of about 70 feet (21 meters). The dimensions of the locks limit the size of ships that can use the canal. For example, commercial supertankers and the supercarriers of the U.S. Navy cannot pass through it.

A 1903 treaty between the United States and Panama gave the United States the right to build and operate the waterway. The United States also received the right to govern an area of land called the Panama Canal Zone on both sides of the canal. For many years, Panama tried to gain control of the canal and the zone. In 1977, Panama and the United States signed a new treaty. As a result of this treaty, Panama received territorial jurisdiction over the zone in 1979. The United States kept administrative control of some military installations and areas necessary to operate and defend the canal. Also as a result of the treaty, Panama took control of the operations of the canal and its associated military installations on Dec. 31, 1999. A second treaty gave the United States the right to defend the neutrality of the canal beyond that date.

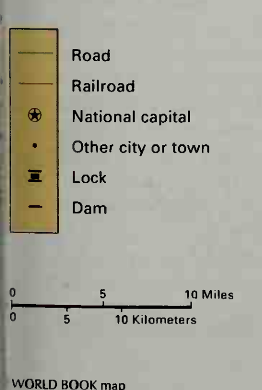
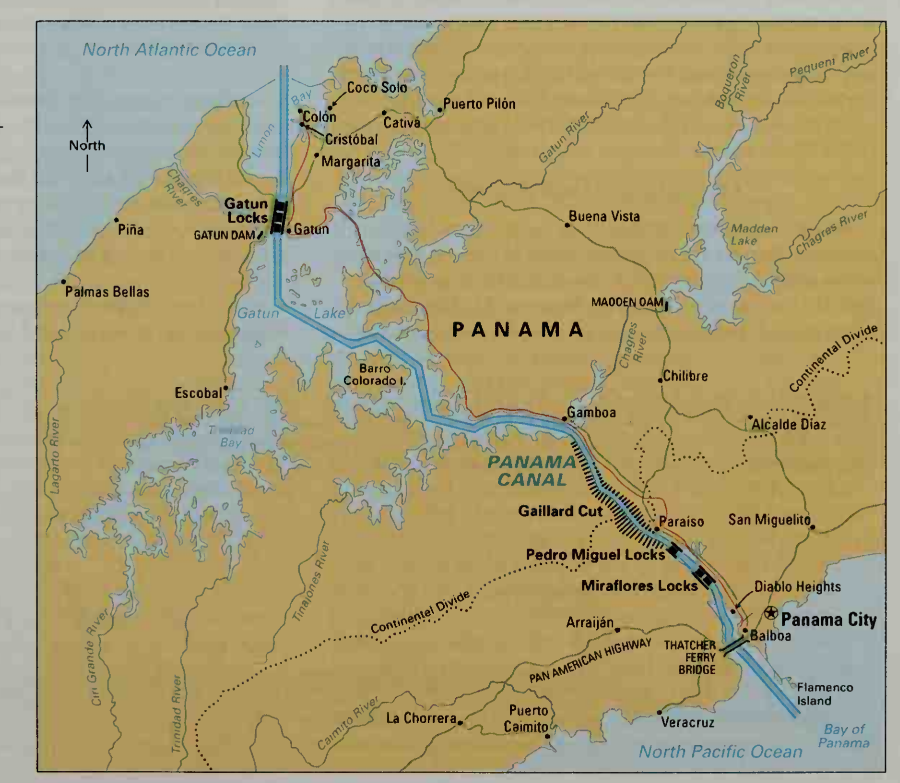
the ship is still in deep water, a canal pilot comes on board from a small boat. The pilot has complete charge of the ship during its trip through the canal. After passing through the breakwater at the entrance to the bay, the ship heads south along the channel, 7 miles (11 kilometers) long, that leads to the Gatun Locks. The shipyards, docks, and fueling stations of Cristóbal line the eastern shore of the bay.

The Gatun Locks (*guh TOON*) look like giant steps. They consist of three pairs of concrete chambers that lift ships about 85 feet (26 meters) from sea level to Gatun Lake. Small electric locomotives called *mules* run on tracks along both sides of the locks. They help to position and stabilize ships in the locks. They also pull and guide small ships through the locks. Large ships go through the locks chiefly under their own power. But locomotives help pull them, and also guide them.

As a small ship approaches the first chamber, its engines are shut off. A large ship approaching the chamber keeps its engines on. Canal workers fasten the ends of the locomotives' towing cables to the vessel. The locomotives then pull a small ship, or help pull a large ship, into the first chamber. Huge steel gates close behind the vessel. Workers open valves that allow water from Gatun Lake to flow into the chamber through openings in the bottom of the lock. During the next 8 to 15 minutes, the rising water slowly raises the ship. When the level of the water is the same as the level of the water in the second chamber, the gates in front of the ship swing outward. The locomotives pull, or help pull, the vessel into the second chamber. Again the water level is raised. This process is repeated until the third chamber raises the ship to the level of Gatun Lake.



Gatun Lake. The canal workers release the cables, and the ship sails out of the locks under its own power. As it heads south across the quiet water of Gatun Lake, it passes the huge Gatun Dam to the west of the locks. This 23-million-cubic-yard (18-million-cubic-meter) earth dam is one of the largest in the world. Gatun Dam created 163-square-mile (422-square-kilometer) Gatun Lake by holding back the waters of the Chagres River. The ship steams across the lake from Gatun Locks to Gamboa, following the 22-mile (35-kilometer) channel that was once the Chagres River Valley.



The tops of trees and hills jut above the water. They were almost submerged when engineers flooded the valley to create Gatun Lake. The violet flowers and green leaves of water hyacinths float on the lake. Their long, coarse stems can become tangled in ship propellers and endanger navigation. A special hyacinth patrol destroys more than 42 million plants a year to keep the channel clear.

The Gaillard (*gill yard*) **Cut.** When the ship reaches the southeastern end of Gatun Lake it enters the Gaillard Cut, 8 miles (13 kilometers) long and 500 feet (150 meters) wide. The cut has a minimum depth of 42 feet (13 meters). *Cut* is an engineering term for an artificially created passageway or channel. The Gaillard Cut runs between Gold Hill on the east and Contractor's Hill on the west. The Gaillard Cut was originally called the *Culebra Cut.* In 1913, it was renamed in honor of David DuBose Gaillard, the engineer in charge of digging between the hills. Dredgers work constantly to keep the channel clear of earthslides. In some years, the dredgers in the

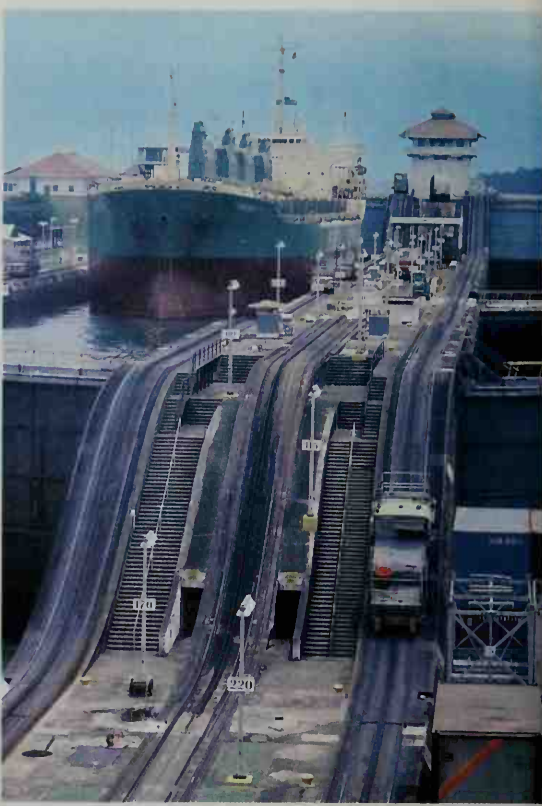
The Pedro Miguel and Miraflores locks. After the ship heads out of the Gaillard Cut, electric locomotives pull, or help pull, it into the Pedro Miguel Locks. These locks lower the vessel 31 feet (9 meters) in one step to Miraflores Lake. The ship sails 1 $\frac{1}{2}$ miles (2.4 kilometers) across the lake to the Miraflores Locks. Here, two chambers lower it to the level of the Pacific Ocean. The distances these chambers must lower the ship depend on the height of the tide in the Pacific. Tides at the Pacific end of the canal rise and fall about 12 $\frac{1}{2}$ feet (3.8 meters) a day. Tides on the Atlantic side change only about 2 feet (60 centimeters) daily.

Out of the locks, the ship heads down the channel, 8 miles (13 kilometers) long, between the Miraflores Locks and the end of the canal. It passes the towns of Balboa, Balboa Heights, and La Boca. The ship also passes under the Thatcher Ferry Bridge, an important link in the Pan American Highway. After the pilot leaves, the vessel enters the Bay of Panama and heads toward the open sea. It has traveled a little over 50 miles (80 kilometers) from the Atlantic to the Pacific in about eight hours.

Importance of the canal



The Panama Canal is an important commercial and military waterway. About 12,000 oceangoing vessels travel through it yearly—an average of about 33 per day. The ships carry about 260 million tons (235 million metric tons) of cargo annually. About 70 percent of the cargo is being carried to or from U.S. ports. Other frequent users of the canal include Canada and Japan.

Until 1999, the United States maintained several military bases to defend the canal. Huge quantities of war materials and thousands of troops passed through the canal during World War II (1939-1945), the Korean War (1950-1953), and the Vietnam War (1957-1975).

Administration and defense

Administration. Panama took over control of the canal on Dec. 31, 1999, under terms of a treaty that had been signed by the United States and Panama in 1977. Prior to the canal's transfer to Panama, a U.S. government agency called the Panama Canal Commission operated and maintained the waterway. In addition, the commission operated public utilities and provided community, sanitation, security, and transportation services. By the time of the transfer, the Panama Canal Commission had more than 7,000 employees, about 95 percent of whom were Panamanian. The commission's board of directors consisted of five Americans and four Panamanians.

After the transfer of the canal to Panama, the Panamanian government placed it under the control of a new

agency created specifically to operate and maintain the waterway. Unlike the old U.S. Panama Canal Commission, the Panama Canal Authority is controlled by a Panamanian board of directors appointed by the president of Panama and approved by the country's legislature. The authority is an extremely powerful agency with the right to manage all its own financial affairs, control its labor force, and make its own laws.

The Panama Canal Authority collects tolls from ships that use the canal. The amount of the toll paid by a merchant ship is generally determined by the ship's cargo space. The toll for certain smaller vessels is based on the length of the vessels. Military ships pay a toll based on their weight.

Defense. International law requires that commercial and military vessels of all nations be allowed to pass through the canal in peacetime. A treaty signed by the United States and Panama in 1977 guarantees that the canal will remain open to all nations even in time of war. The agreement gives the United States the right to use military force if necessary to protect the neutrality of the canal.

History

Early efforts. Hundreds of years before the Panama Canal was completed, people of many lands dreamed of building a canal across Central America. As early as 1517, Vasco Núñez de Balboa, the first European to reach the Pacific, saw the possibility of a canal connecting the Atlantic and Pacific oceans.

Throughout most of the 1800's, Nicaragua was the chief center of efforts to build a canal. Both the United States and the United Kingdom considered a canal across Nicaragua. During the 1840's, the two nations almost went to war because of disputes over which one would control the proposed canal. In 1850, in the Clayton-Bulwer Treaty, they agreed to protect the neutrality of a canal to be built somewhere across the Central American isthmus. See **Clayton-Bulwer Treaty**.

During that period, present-day Panama was a province of Colombia. Colombia feared that the United Kingdom would try to seize Panama for use as a canal site. Colombia signed a treaty with the United States in 1846. The United States agreed to guard all trade routes across Panama and to preserve Panama's neutrality.

The Panama Railroad. During the California gold rush that began in 1849, the Isthmus of Panama became an important route between the Eastern United States and California. Many prospectors sailed from Atlantic Coast ports to Panama, crossed the isthmus by boat, on mules, and on foot, and then took another ship for California. In 1850, Colombia permitted a group of business executives from New York City to build a railroad across the isthmus. The line was completed in 1855 at a cost of $8 million. It linked Colón on the Atlantic side and Panama City on the Pacific side.

The French failure. In 1878, Colombia granted a French adventurer named Lucien Napoleon Bonaparte Wyse the right to build a canal across Panama. He sold the right to a French company headed by Ferdinand Marie De Lesseps, who had directed the construction of the Suez Canal. The French also bought control of the Panama Railroad for $20 million. The company began digging in 1882. The French planned a canal that would run at sea level between the Atlantic and Pacific, and so would need no locks. In 1886, the problems of building a sea-level canal forced the French to decide to build a canal similar to the present one. De Lesseps and his assistants planned most of the project carefully and carried out some of it efficiently. However, the French wasted great quantities of material and effort. A group of dishonest politicians who supported De Lesseps stole large amounts of money from the canal company. The French engineers lacked the proper tools to complete such a huge digging job. In addition, scientists did not know how to fight the epidemics of tropical diseases that hit the workers.

De Lesseps's company went bankrupt in 1889, after digging out some 76 million cubic yards (58 million cubic meters) of earth. A second French firm, the New Panama Canal Company, took over the property and franchise in 1894. But the new company made only half-hearted efforts to continue digging, in order to keep the franchise until a buyer could be found.

The United States and the canal. A group of United States business executives began working on a canal across Nicaragua in 1889. But the group ran out of money soon after beginning the Nicaraguan project. Both the American and French groups tried to sell their rights and property to the United States government. However, American railroad executives opposed construction of any Central American canal because they feared competition from shipping lines that would use the canal. As a result, the United States government took no action on either project.

During the Spanish-American War in 1898, the United States Navy sent the battleship *Oregon* from San Francisco to Cuba to reinforce the Atlantic Fleet. The *Oregon* had to sail nearly 13,000 miles (20,900 kilometers) around the tip of South America. The trip would have been only about 4,600 miles (7,400 kilometers) long through a canal. This fact helped convince the United States Congress that a canal across Central America was essential for national defense.

In 1899, Congress authorized a commission to survey possible canal routes. The commission favored Nicaragua, because a canal there would require less digging than one across Panama. But the French company offered to sell its Panama rights and property and the Panama Railroad for $40 million. Philippe Bunau-Varilla, of the French company, convinced leading Americans that Nicaragua's volcanoes presented the danger of earthquakes and that Panama was safer. In 1902, Congress gave President Theodore Roosevelt permission to accept the French offer if Colombia would give the United States permanent use of a canal zone. Congress acted after the United States and the United Kingdom had replaced the Clayton-Bulwer Treaty with the Hay-Pauncefote Treaty. This treaty gave the United States sole right to build and operate a canal across Central America. See **Hay-Pauncefote Treaty**.

In 1903, U.S. Secretary of State John Hay signed a canal treaty with a Colombian representative, Tomás Herrán. The treaty provided that the United States would give Colombia an initial payment of $10 million and pay $250,000 annual rent for the use of the zone. But the Colombian legislature refused to approve the treaty because it felt that this was not enough money.

President Theodore Roosevelt visited the construction site of the Panama Canal in 1906. He wrote his son about the Gaillard Cut, saying, "They are eating steadily into the mountain . . . ."

A group of Panamanians feared that Panama would lose the commercial benefits of a canal across the isthmus. The French company worried about losing the sale of its property to the United States. The Panamanians, with the help of the French and some encouragement from the United States, revolted against Colombia on Nov. 3, 1903, and declared Panama independent. In accordance with its 1846 treaty with Colombia, the United States sent ships to Panama to protect the Panama Railroad. Marines landed in Colón, and prevented Colombian troops from marching to Panama City, the center of the revolution. On Nov. 6, 1903, the United States recognized the Republic of Panama. Less than two weeks later, Panama and the United States signed the Hay-Bunau-Varilla Treaty. It gave the United States permanent, exclusive use and control of a canal zone 10 miles (16 kilometers) wide. In return, the United States gave Panama an initial payment of $10 million, plus $250,000 a year, beginning in 1913. The United States also guaranteed Panama's independence. The United States took over the French property in May 1904.

Victory over disease. The greatest obstacle to building the Panama Canal was disease. The Isthmus of Panama was one of the most disease-ridden areas in the world. In 1904, Colonel William C. Gorgas took charge of improving sanitary conditions in the Canal Zone. Gorgas, an American physician, had become famous for wiping out yellow fever in Havana, Cuba, after the Spanish-American War.

Gorgas began a campaign to destroy the types of mosquitoes that carried malaria and yellow fever. The first two years of canal building were devoted largely to clearing brush, draining swamps, and cutting out large areas of grass where the mosquitoes swarmed.

By 1906, Gorgas had wiped out yellow fever and eliminated the rats that carried bubonic plague in the Canal Zone. By 1913, he had also reduced the rate of deaths caused by malaria.

Cutting through the isthmus. Roosevelt appointed a civilian commission to lead the canal project. In 1906, Congress decided to build a canal with locks, rather than the sea-level canal that the French had originally planned. Engineers believed a canal with locks would be cheaper and faster to build. They also felt a canal with locks would control the Chagres River's floodwaters better than a sea-level canal would. The work progressed slowly, chiefly because of disagreements among the commission members. In 1907, Roosevelt put Colonel George W. Goethals, an Army engineer, in charge of the project and the Canal Zone.

The construction task involved three major engineering jobs. The builders had to excavate the Gaillard Cut, build a dam across the Chagres River to create Gatun Lake, and build the canal's locks. The biggest job was digging the Gaillard Cut. The hills through which the cut runs consist of a soft volcanic material, and digging into them was like digging into a pile of grain. As soon as workers dug a hole, more rock and earth would slide into the space, or push up from below. The engineers had expected to remove about 95 million cubic yards (73 million cubic meters) of earth and rock to build the canal. They actually dug out about 211 million cubic yards (161 million cubic meters). Some of this was used later in the construction of Gatun Dam.

At the height of the work in 1913, more than 43,400 people worked on the Panama Canal. Three-fourths were blacks from the British West Indies. Other workers came from Italy and Spain. Most of the clerical and skilled workers came from the United States.

The oceans united. The main work of building the Panama Canal was completed in 1914. On August 15, 1914, a passenger-cargo ship owned by the Panama Railroad Company, the S.S. *Ancon,* made the first complete trip through the canal. The ship sailed from the Atlantic to the Pacific and made a reality of the canal slogan—"The Land Divided, the World United." A giant landslide in the Gaillard Cut closed the canal for several months in 1915 and 1916. It was the last major interruption in the operation of the Panama Canal. President Woodrow Wilson proclaimed the official opening of the Panama Canal on July 12, 1920.

The canal cost the United States about $380 million. This included the $40 million paid to the French company, the $10 million paid to Panama, and $20 million for sanitation. The remaining $310 million was spent for the actual construction work.

The canal since 1920. The Madden Dam, completed in 1935, was the first major improvement on the canal. The dam lies across the Chagres River, east of the canal. It created 22-square-mile (57-square-kilometer) Madden Lake, which stores water for use in Gatun Lake. The dam also holds back the floodwaters of the Chagres River during the rainy season.

In 1936, the United States agreed to raise its annual payments to Panama to $430,000, which made up for a devaluation of the dollar. In 1955, the payments were increased to about $2 million a year.

During the 1950's, engineers began to widen the Gaillard Cut from 300 to 500 feet (91 to 150 meters). This project was completed in 1970.

From the 1920's to the 1970's, the United States and Panama had many disputes concerning U.S. control over the Panama Canal Zone. The Panamanians regarded the zone as part of their country. They believed the 1903 treaty, which established the zone, was unfairly favorable to the United States. Some Panamanians also resented the large number of U.S. military bases in the zone. See **Panama Canal Zone**.

In 1971, Panama and the United States began negotiations for a new treaty to replace the 1903 pact. In 1977, the two nations signed two new treaties. One of the treaties provided for the transfer of territorial jurisdiction over the Panama Canal Zone to Panama in 1979. This treaty also provided for Panama to take control of canal operations in 1999. The other agreement gave the United States the right to defend the neutrality of the canal beyond 1999.

Many Americans opposed giving up control of the canal and the zone, which they regarded as United States property. Other Americans favored the treaties. They believed continued United States control would harm relations with Latin American nations. The two agreements were approved by Panama's voters in 1977 and by the U.S. Senate in 1978. The treaties took effect in 1979.

Panama formally took control of the canal on Dec. 31, 1999. Former President Jimmy Carter represented the United States at ceremonies held earlier that month to mark the transfer of the canal. Carter had played a leading role in negotiating the canal treaties. Steve C. Ropp

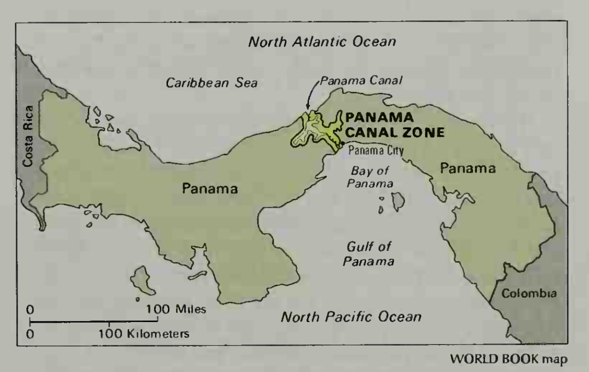
Panama Canal Zone was a strip of land across the Isthmus of Panama that was governed by the United States from 1903 to 1979. The Panama Canal, a waterway that connects the Atlantic Ocean and the Pacific Ocean, cuts through the center of the zone. The zone came under Panama's control as a result of a treaty with the United States that went into effect in 1979.



The Panama Canal Zone was established in 1903 by a treaty between the United States and Panama. The pact gave the United States permanent control of a zone of land 10 miles (16 kilometers) wide and about 40 miles (64 kilometers) long. This grant was made for the construction and operation of the proposed Panama Canal, which the United States completed in 1914. The area designated by the treaty excluded what are now Panama City and Colón.

Later agreements between Panama and the United States added Madden Lake and Trinidad Bay to the area under U.S. control. Before Panama took control, the zone covered 647 square miles (1,676 square kilometers), including 275 square miles (712 square kilometers) of water. The zone had a population of about 40,000, of whom about 36,000 were U.S. citizens. Most of the people worked for the U.S. Army, the Canal Zone government, or the Panama Canal Company, a U.S. government corporation that operated the canal. The U.S. citizens were called *Zonians.*

The United States and Panama had many disputes over U.S. control of the Panama Canal Zone. The Panamanians considered the zone part of their country. Crowds of Panamanians rioted in 1958 and 1959, demanding the right to fly their country's flag in the zone. In 1962, Panama and the United States agreed to fly the flags of both countries side by side in selected civilian areas of the zone. The United States also granted higher wages to Panamanians in the zone. Previously, Panamanians were paid less than Americans were for the same work.

Riots broke out again in 1964, and 20 Panamanians and 4 Americans were killed. Panama then cut off diplomatic relations with the United States. Relations between the two nations were restored after the United States agreed to negotiate a new treaty to replace the 1903 pact. During the following years, three treaties were drafted. However, neither government approved any of those pacts.

During the 1970's, the two nations again held negotiations for a new treaty. In 1977, they signed two new treaties. One provided for Panama to assume territorial jurisdiction over the zone in 1979. It also provided for Panama to assume control over the operations of the canal and its associated military installations on Dec. 31, 1999. The other treaty gave the United States the right to

defend the canal's neutrality. The agreements were approved by Panama's voters in 1977 and by the United States Senate in 1978. Both treaties went into effect in 1979. Steve C. Ropp

Panama City (pop. 389,172) is the capital and largest city of Panama. It lies at the Pacific Ocean end of the Panama Canal and is a crossroads of world trade. For location, see **Panama** (map).

Panama City consists of widely different sections. A historic section occupies a peninsula on the Pacific coast. This section contains narrow streets and buildings that date to the late 1600's. Spaniards built this section to replace the original Spanish settlement, which was destroyed by pirates. Ruins of the original settlement lie about 5 miles (8 kilometers) east of the peninsula. Several treelined boulevards cross downtown Panama City. This area contains a broad promenade along the seafront. Interesting downtown buildings include the Palace of Justice, the Presidential Palace, and the Museum of the Panamanian Man. The nearby ATLAPA (Atlantic and Pacific) Convention Center, which can hold 16,000 people for exhibitions, overlooks the ocean.

The city's wealthy people, who include descendants of immigrants from many countries, live in tall, modern buildings or in magnificent residences surrounded by tropical gardens. Most of these homes are located on the outskirts of the city and in the suburbs. Many poor Panamanians live in sprawling slums in the city.

Most workers hold jobs in government or international trade, or with the Panama Canal. Panama City is an important banking center, and more than 100 foreign banks have branches there. Tourism also is a chief source of income. The city's industries include food processing and the manufacture of clothing. The Pan American Highway links the city with other parts of Central America, and with Mexico and the United States.

Panama City was founded in 1519 by Pedro Arias de Ávila, a Spanish adventurer. In 1671, the English pirate Henry Morgan led 1,400 men against Panama City and destroyed it. But the city was rebuilt in 1673. The Panama Canal opened in 1914. It made the city a center for world trade (see **Panama Canal**). Nathan A. Haverstock

Pancreas, *PAN kree uhs,* is a body organ found in human beings and all animals with backbones. It produces digestive juices required to break down foodstuffs. It also produces *insulin* and *glucagon,* two hormones needed to regulate the body's sugar balance and *metabolism* (see **Metabolism**).

The human pancreas is a pinkish-yellow gland about 6 to 8 inches (15 to 20 centimeters) long, 1 $\frac{1}{2}$ inches (3.8 centimeters) wide, and 1 inch (2.5 centimeters) thick. It lies crosswise, behind the stomach. The first part of the small intestine, the *duodenum,* loops around the pancreas. Digestive juices secreted by the pancreas flow through a duct into the duodenum. The secretion contains water and salts that aid the digestive process and neutralize stomach acids. Enzymes in the secretion help to break down proteins, starches, and fats.

Small clusters of special cells called the *islets* (or *islands*) *of Langerhans* are scattered throughout the pancreas. The cells secrete hormones directly into the bloodstream. There are several types of islet cells, including *alpha cells* and *beta cells.* Insulin is produced by beta cells. Insulin travels through the bloodstream to cells throughout the body. It enables cells to take in and use glucose from the blood. Glucose, a sugar, is the main fuel of the body's cells. If the pancreas secretes too little insulin, a serious form of the disease diabetes mellitus results (see **Diabetes**).

The alpha cells secrete glucagon. Glucagon causes the liver to release stored glucose into the bloodstream. Glucagon and insulin work together to regulate the level of glucose in the blood. Charles Liebow

Pancreatitis, *PAN kree uh TY tihs,* is a disease that involves inflammation of the pancreas. People who have pancreatitis experience attacks of sudden, severe pain in the abdomen. Attacks usually occur after large meals and may become chronic. Chronic pancreatitis can lead to diabetes, inability to digest food, or cancer of the pancreas. Acute attacks often result in death.

Pancreatitis primarily affects the portion of the pancreas that produces digestive enzymes. Normally, these enzymes flow through a duct into the small intestine, where they break down food. In people with pancreatitis, however, the inflamed pancreas releases enzymes into its own tissue instead of into the duct. The enzymes break down the tissue of the pancreas and can continue to do so until the entire organ is destroyed.

Heavy or prolonged drinking of alcoholic beverages increases the risk of developing pancreatitis. People who smoke cigarettes and those who have gallstones also are at special risk. Some cases of pancreatitis have been associated with hereditary factors.

Treatment of acute pancreatitis requires hospitalization. People with chronic pancreatitis should eat low-fat foods and avoid drinking alcohol. Charles Liebow

Panda is the name of two species of Asian mammals that differ greatly in appearance. The *giant panda* is a large, black-and-white animal. The *red panda,* also called the *lesser panda,* is reddish-brown and much smaller. Both species live in bamboo forests on upper mountain slopes of western and southwestern China. The red panda also lives in Nepal, northern India, and northern Myanmar. Giant pandas are rare and are protected by law in China.

Zoologists disagree about how closely the giant panda and the red panda are related to each other. They also disagree on whether to classify pandas in the raccoon family, in the bear family, or in a family of their own. Red pandas have many characteristics in common with raccoons. These include fur markings and the ability to grasp objects with the front paws. Giant pandas resemble bears in size, body shape, general appearance, and the ability to stand erect on their hind legs. In addition, molecular studies indicate that DNA (deoxyribonucleic acid) of red pandas resembles that of raccoons, and the DNA of giant pandas more closely resembles that of bears. Many zoologists studying pandas in the wild, however, argue that the two species of pandas should be placed in a family of their own.

Flip Schulke, Black Star

The giant panda commonly weighs from 200 to 300 pounds (90 to 140 kilograms). It often eats sitting upright with its hind legs stretched out. The smaller red panda weighs only from 6 to 12 pounds (2.7 to 5.4 kilograms).

Tierbilder Okapia

Pandas eat bamboo. The giant panda eats bamboo shoots, as well as bamboo stems and leaves. The red panda eats bamboo leaves. Pandas grasp the bamboo between their fingers and an "extra thumb." This thumb, which is a bone covered by a fleshy pad, grows from the wrist of each forepaw. Pandas also have true thumbs, which they use as fingers.

Unlike most plant-eating animals, pandas have inefficient digestive systems that cannot easily change plant food into energy. As a result, pandas must eat large quantities of bamboo to get enough energy. For example, giant pandas eat as much as 85 pounds (39 kilograms) of bamboo shoots per day.

The giant panda has a white, chubby body with black legs and a broad band of black across the shoulders. It has a large, round head; small, black ears; and a white face with black patches around each eye. This panda commonly grows to about 5 to 6 feet (1.5 to 1.8 meters) long and has a short tail. Adults weigh about 200 to 300 pounds (90 to 140 kilograms).

The female giant panda gives birth once a year to one or two cubs. Panda cubs are extremely tiny, weighing only about 5 ounces (140 grams) at birth. The mother, who normally spends about 12 hours per day feeding, stays with the newborn cub for up to 10 days without feeding. Cubs normally nurse for about a year and may remain with the mother for more than two years.

The red panda has long, soft fur, and a bushy tail with rings like that of a raccoon. This panda weighs about 11 pounds (5 kilograms) and grows to about 2 feet (61 centimeters) long, not including the tail. It has a pale face with a rusty-red streak that curves downward from each eye. The red panda climbs easily and sleeps in a tree most of the day. It searches for food at dawn and dusk. Red pandas are more likely than giant pandas to eat foods other than bamboo, such as fruits and berries.

Protecting pandas. Widespread cutting of forests for wood and farmland in China has destroyed a large part of the habitat of pandas. The Chinese government has tried to protect pandas by establishing reserves of bamboo-rich public land for them. Fairly large reserves are needed because every 15 to 120 years, bamboo plants flower and produce seeds, then die. It takes several years for the seeds to grow into plants that can provide food for pandas. Since the late 1970's, such periodic die-offs of bamboo have led to the deaths of hundreds of giant pandas from starvation. Scientists estimate that fewer than 1,000 giant pandas remain in the wild. The number of red pandas remaining is unknown.

Other efforts to ensure the survival of giant pandas have focused on breeding them in zoos. However, most breeding attempts have failed. In 1972, China gave two giant pandas to the United States. These two pandas—Ling-Ling, a female; and Hsing-Hsing, a male—were placed in the National Zoological Park in Washington, D.C. Before Ling-Ling died in 1992, she gave birth to cubs several times, but each cub died shortly after birth. Hsing-Hsing died in 1999. Researchers continue to study pandas in an effort to find better ways to breed the animals in zoos and to protect them in the wild.

Pandit, Vijaya Lakshmi, *PUHN diht, vih JY uh LAHK shmee* (1900-1990), one of India's most famous women, became known for her work in government and for her interest in the women's movement. Madame Pandit was appointed ambassador to the Soviet Union in 1947, and ambassador to the United States in 1949. From 1953 to 1954, she served as the first woman president of the United Nations General Assembly. She then became Indian high commissioner in the United Kingdom. Madame Pandit became ambassador to Ireland in 1955 and ambassador to Spain in 1958. She held both posts until 1961. Madame Pandit served as governor of the Indian state of Maharashtra from 1962 to 1964. She served in India's Parliament from 1964 to 1967 and retired from public life in 1968.

Madame Pandit was born in Allahabad. Like her father and brother, Motilal and Jawaharlal Nehru, she took a prominent part in India's struggle for independence and was jailed several times. Her brother served as India's prime minister from 1947 to 1964. Indira P. Gandhi—her niece and Jawaharlal's daughter—became prime minister of India in 1966. In 1977, Madame Pandit campaigned against her niece's political party because she opposed the way it had restricted freedom in India.

Pandora, *pan DAWR uh,* in Greek mythology, was the first woman. Zeus, the king of the gods, ordered Pandora created as a punishment for men. Zeus was angry because men had received fire stolen from the gods by Prometheus (see **Prometheus**). Zeus ordered Hephaestus, the blacksmith of the gods, to create Pandora. The gods and goddesses then adorned her with many gifts to make her alluring. The name *Pandora* means *all gifts* in Greek.

Zeus gave Pandora to Prometheus' brother Epimetheus. In spite of Prometheus' warnings, Epimetheus gave her to men. Pandora's curiosity led her to open a jar, and all types of evil, including disease and hard labor, escaped to plague humanity. Only Hope did not escape from the jar. Ancient Greek sources are vague about the origin of the jar.

Many writers have noted the resemblance between Pandora and Eve in the Bible. In 1508, the Dutch author Desiderius Erasmus first used the image "Pandora's box" instead of the traditional jar or vase. Pandora's box has come to symbolize any object or situation that has a great potential for evil. Justin M. Glenn

Pangolin, *pang GOH luhn,* is the name of several species of animals that resemble anteaters and armadillos. Pangolins live in southeastern Asia, Indonesia, and parts of Africa south of the Sahara. Like anteaters, pangolins are toothless and have long, narrow snouts, long tails, and sticky, ropelike tongues that they can thrust far out to catch the ants on which they feed. Pangolins have coats of mail formed by overlapping horny scales, instead of the coarse hair of anteaters. These scales are various shades of brown.

Pangolins vary in length from 3 to 5 feet (0.9 to 1.5 meters), depending on the species. The *long-tailed pangolin* of western Africa lives in trees. Its tail is about two-thirds of its total length. All pangolins have large, strong claws on their forefeet, which they use to rip open the nests of ants and termites.

Pangolins can roll themselves into tight balls so heavily armored that few enemies can harm them. They are inoffensive animals, but when captured they may lash out with their scaled tails.

Pangolins are much hunted for their excellent meat. But because they are shy and look for food only at night, they have been saved from extinction.

Scientific classification. Pangolins make up the family Manidae. Asian pangolins make up the genus *Manis.* African pangolins make up the genus *Phataginus.* The scientific name for the long-tailed pangolin is *Phataginus tetradactyla.*

Panic disorder is a mental illness characterized by sudden, unexpected attacks of intense fear or terror. The attacks are accompanied by symptoms of bodily illness. People commonly experience panic when facing danger. In people with panic disorder, however, attacks of panic occur without obvious reason.

Most panic attacks last several minutes. The person may fear that he or she is losing control of thoughts and actions and may experience an overwhelming fear of death. Physical symptoms include shortness of breath, dizziness, trembling, sweating, a choking sensation, nausea, numbness or a tingling sensation, hot flashes, and chest pain. Generally, doctors make a diagnosis of panic disorder only if a person has had four or more panic attacks within a four-week period. However, one

attack is sufficient for a diagnosis if it results in long-lasting, severe fear of having another attack.

People with panic disorder become very depressed and some become so depressed they commit suicide. Some patients develop *agoraphobia* (the fear of open spaces) and may stay inside their homes for years. The symptoms of a panic attack may mimic other serious disorders, especially heart attack.

The cause of panic disorder is not known for certain. Studies suggest that genetic factors are responsible. The disorder usually first strikes before age 30.

Doctors treat panic disorder with medications used to treat anxiety and depression. Psychotherapy and behavior therapy are also effective treatments.

Pankhurst, Emmeline Goulden (1858-1928), led the fight for women's voting rights in Britain. With her husband, Richard M. Pankhurst, she helped form the Women's Franchise League in 1889. In 1903, she helped organize the National Women's Social and Political Union, with the slogan "Votes for Women." In their bold program, Mrs. Pankhurst's followers differed from older "suffragettes." They staged parades and engaged in such violence as window-breaking to gain attention. She and her followers, including her daughters Christabel and Sylvia, suffered rough handling and imprisonment. During World War I (1914-1918), they turned to patriotic work. Women received equal voting privileges in Britain the year of Mrs. Pankhurst's death. She was born in Manchester, England. Louis Filler

Panmunjom, *pahn moon jahm,* is the site of the truce talks that ended the Korean War in 1953. It lies in a neutral area, called the *Demilitarized Zone,* between North Korea and South Korea (see **Korea** [political map]). Before the truce talks, Panmunjom was a small civilian village. Today, it is the point of contact between North and South Korea, and between United States and North Korean military representatives. The Panmunjom area is guarded by North Korean forces on the north side, and South Korean and U.S. troops on the south side.

The Korean War truce talks took place between the United Nations Command—represented by the United States—on one side, and North Korea and China on the other side. The talks began in July 1951 in Kaesong, a city under North Korean control. In October, the talks were moved to Panmunjom, situated in neutral territory. The talks led to the signing of a truce agreement on July 27, 1953. Chong-Sik Lee

Pansy is a commonly cultivated type of violet. The beautiful flowers may be purple, violet, blue, yellow, white, brown, deep red, or a mixture of these colors. The pansy is a low-growing plant that grows best in a moist location with some shade. Most garden varieties live only a year. Some varieties are *perennials*—that is, they live at least three years. The word *pansy* comes from the French word *pensée,* which means *thought.*

The pansy is also called the *heartsease, ladies-delight,* and *stepmother's flower.* The *European wild pansy,* which is also known as the *field pansy* or *Johnny-jump-up,* is a perennial with much smaller flowers.

Scientific classification. The pansy belongs to the violet family, Violaceae. James S. Miller

Pantheism, *PAN thee ihz uhm,* is the belief that the essence of God is in all things. It is often associated with nature religions, including many American Indian, African, and ancient Middle Eastern religions. In these religions, gods are connected with such things as storms, stars, the sky, the sea, fertility, and skill in hunting. In the Japanese Shinto tradition, gods are identified with natural objects, including rocks and trees. In a more general sense, pantheism refers to any religious philosophy that identifies God with nature. Mark Juergensmeyer

Pantheon, *PAN thee ahn,* is a well-preserved ancient temple in the center of Rome. It was completed under the rule of the Roman emperor Hadrian about A.D. 126. Hadrian dedicated the temple to all the Roman gods. Its name comes from the Greek word *pantheion,* which means *place for all gods.* The temple served as a Christian church from 609 until 1885. It then became a national shrine and the burial place for Italian national heroes. Famous Italians buried there include King Victor Emmanuel I and the Renaissance painter Raphael.

The Pantheon was constructed largely of brick and concrete. It is a circular building that measures about 142 feet (43 meters) in diameter. It has a dome roof that rises about 142 feet (43 meters) above the floor at its highest point. A rectangular *portico* (porch) extends from the entrance of the building. The portico has a triangular roof that is supported by a row of eight Corinthian columns. Many of the engineering techniques used to build the Pantheon are still used today.

The Pantheon was one of the first buildings to emphasize interior space rather than exterior form. The interior is beautifully and evenly lit by an *oculus* (opening) that measures 30 feet (9 meters) in diameter at the top of the dome. The proportions of the central space have been highly praised for their harmony. The bronze doors at the entrance and some of the marble used in the interior decoration are part of the original construction of the Pantheon. William J. Hennessey

Pantograph, *PAN tuh graf,* is the name of a mechanical drawing instrument which copies, traces, or cuts in duplicate a design, map outline, or drawing. It is made of four bars or rods held together by adjustable pins. One end of the pantograph is held stationary. One tracing point is moved over the design to be copied, following its outlines. Another point will then move in unison with this point, copying or cutting a duplicate outline. The pantograph can be set, by using adjustable pins, to copy in any size. Todd I. Blue

Pantomime refers to acting without words. It comes from the Greek words meaning *all mimic.* All actors

today use a certain amount of pantomime. Many plays have silent passages in which only the movements of an actor's arms, legs, or face express ideas. In fact, all expressive movement of the body could be considered pantomime. Ballet and opera also use some pantomime.

Pantomime began in ancient Rome. It had a single dancer who was supported by musicians and a chorus. The chorus narrated short versions of well-known Greek or Roman heroic tales, while the dancer used masks and costumes to act out various characters.

During the 1700's, pantomime plays were popular in England and France. They owed much to a popular type of Italian comedy, *commedia dell'arte,* and its stock characters. Early English pantomimes always used a servant clown called Harlequin, a lovable father called Pantaloon, and a lively daughter called Columbine. In the early 1800's, English pantomimes added a new stock character called Clown. These shows combined music and songs, dancing and acrobatic acts, and had elaborate scenery and stage effects.

During the mid-1800's, George L. Fox, an American pantomimist, was popular as Humpty-Dumpty. Fox used stage productions of fairy tales or nursery stories. Today, Christmas entertainment in the United Kingdom includes similar pantomimes. Don B. Wilmeth

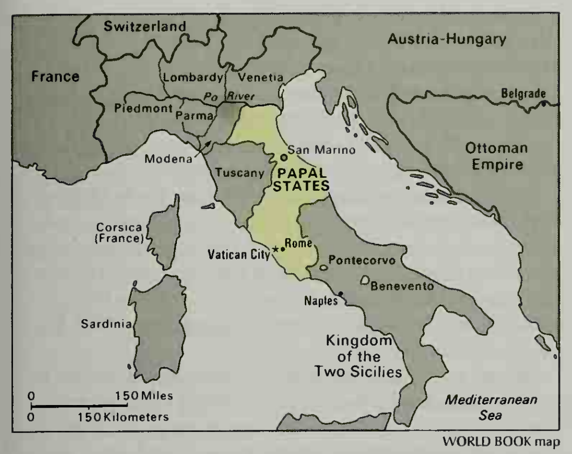
Pap test is a procedure for detecting cancer cells and abnormalities that could become cancerous in the female genital tract. It is most commonly used to evaluate the condition of the *cervix,* which includes the bottom portion and the opening of the uterus. The test is also called the *Papanicolaou test* and *Pap smear test.* George Papanicolaou, a Greek-born physician, developed the procedure in the United States from the 1920's to the 1940's. Wide-spread use of the Pap test has helped to greatly reduce the death rate from cancer of the cervix.

Before cancer develops in the cervix, the cells of the cervix go through many precancerous changes. These changes typically take several years. If a woman has Pap smear screenings regularly, precancerous abnormalities and early stages of cancer can be detected while these problems can be easily treated. With regular follow-up examinations, the woman can usually avoid developing *invasive cancer* (cancer that grows deeply into tissues).

A Pap smear can be performed in a physician's office. The procedure causes no pain and little discomfort. The physician collects a sample of cells from the cervix with a cotton swab, wooden scraper, or small brush. The physician then places the sample on a glass slide and sends it to a medical laboratory for examination. If abnormal cells are detected, the physician may examine the cervix through a type of microscope called a *colposcope* (pronounced *KAHL puh skohp*). If the physician finds abnormalities, a *biopsy* (removal and examination of tissue) will be performed to reach a diagnosis.

Women 18 years of age or older should have Pap smears taken annually. If a girl has sexual intercourse before the age of 18, she should begin having Pap smears earlier. Women who have had an abnormal Pap smear may need to be tested more frequently than once a year. Vicki Seltzer



Papacy. See Pope.

Papal States was the name given to territory once ruled by the pope of the Roman Catholic Church. The pope exercised *temporal* (economic, military, and political) control over the Papal States. Most of the states were located in central Italy, with some lands in France for a time. Today, the pope has temporal control only over the 109 acres (44 hectares) of Vatican City, an independent country within the boundaries of Rome.

The Papal States originated in 756 with land that Pepin the Short, king of the Franks, gave to Pope Stephen II. The Papal States began to grow during the reign of Saint Leo IX in the mid-1000's. The states expanded the most in the 1200's, particularly under the leadership of Pope Innocent III. The Papal States declined in political and economic strength during the 1600's and 1700's.

In 1809, Emperor Napoleon I of France annexed the Papal States and made Pope Pius VII a prisoner. After Napoleon's defeat, the Congress of Vienna restored most of the states to the pope in 1815. However, the return was temporary. Residents of the Papal States revolted against papal control in 1831, in 1848 and 1849, and again in 1860. During the revolt of 1860, Victor Emmanuel II conquered central Italy, and in 1861 he declared the formation of the Kingdom of Italy. Victor Emmanuel became its first king. Only the land immediately surrounding Rome remained under the control of the church. The establishment of the Kingdom of Italy began a period of political and religious conflict between the popes and the Italian government known as the Roman Question.

In 1870, French forces stationed in Rome withdrew, and Victor Emmanuel captured the city. He asked Roman citizens whether the city should become the political capital of a united Italy. The people voted for unification, thus effectively ending the Papal States as a distinct church-controlled territory. Pope Pius IX shut himself up in the Vatican in protest and referred to himself as a prisoner.

WORLD BOOK map

The Papal States before 1870 were large and important tracts of land in the heart of Italy. Today, the Holy See has temporal power only over Vatican City in Rome.

The Roman Question was finally resolved in 1929. In that year, an independent Vatican City state was established through an agreement called the Lateran Treaty. The treaty was made between Pope Pius XI and the Italian government. Under its terms, all financial claims between the two sides were settled, with Italy presenting a payment of cash and bonds to the church. The papacy, in effect, gave up its claims to the territory of the Papal States. Vatican City was to be fully independent. The church was to have exclusive jurisdiction within its boundaries, and the territory was always to be considered neutral and inviolable. In a separate *concordat* (agreement) signed at the same time, the Italian government accepted both the church's status as the official state religion and the church's jurisdiction in Italy over such matters as marriage and divorce.

In 1984, the Italian government and the Vatican ratified a revised version of the concordat. The revised version retained the independence of Vatican City but ended other church privileges, including the church's status as the state-supported religion in Italy. Ronald Burke

Papaya, *puh PY uh,* is a nutritious tropical fruit that has edible flesh and seeds. People usually eat the fruits fresh for breakfast, for dessert, or as an ingredient in salads.

Papaya flesh is a rich source of vitamins A and C, as well as potassium and calcium. In addition, green immature papayas yield papain, a substance used to aid digestion. Ripe papayas have little or no papain. People obtain this substance by drying the sticky, white milk that the fruits release when their skin is scratched.

Papayas vary in shape, with many appearing round or oval. Most grow between 5 and 6 inches (13 and 15 centimeters) long and weigh about 1 pound (0.5 kilogram). The fruit's smooth skin generally has greenish-yellow to orange coloring when ripe. Its flesh varies from 1 to 2 inches (2.5 to 5 centimeters) thick and ranges from light yellow to deep salmon pink in color. A mass of round, black, wrinkled seeds cling to inner walls of the flesh.

Papayas grow on slender, hollow-stemmed plants that may reach a height of 25 feet (8 meters) or more. The

plants grow best in fertile, well-drained soil. They develop quickly from seeds and begin to bear fruit 9 to 12 months after planting.

The papaya is native to tropical regions of North and South America. But people grow the fruit commercially in many warm areas around the world. Brazil, Chile, Indonesia, India, and Mexico rank as the world's leading producers. In the United States, growers cultivate papayas in Hawaii and Florida.

In New Zealand and some other English-speaking countries, papayas are also called *pawpaws.* However, papayas are not the same as the pawpaw fruit of the southern United States (see **Pawpaw**). Michael J. Tanabe

Papen, *PAH puhn,* **Franz von** (1879-1969), was a German politician who helped make Adolf Hitler head of the German government in 1933. Papen persuaded Paul von Hindenburg, Germany's president, to appoint Hitler *chancellor* (prime minister). Papen did not belong to Hitler's Nazi Party, which had become Germany's largest political force by 1933. Papen, who had been forced to resign as chancellor in 1932, wanted to use the Nazis to stabilize Germany's government. But he hoped that he and his fellow conservatives would keep the real power. However, Hitler quickly made himself dictator.

Papen was born to an aristocratic family on Oct. 29, 1879, in Werl, near Dortmund. He gained political power through friendship with Hindenburg. When Hitler took power, Papen became vice chancellor. Papen served as Germany's special minister and ambassador to Austria from 1934 to 1938 and as its ambassador to Turkey from 1939 to 1944. In Turkey, he organized Nazi spy operations during World War II (1939-1945). In 1946, Papen was found innocent of war crimes at trials held in Nuremberg, Germany, by the nations that defeated Germany in the war. But German courts imprisoned him until 1949. Paper is one of our most important industrial products. Books, magazines, and newspapers are printed on paper. Data obtained from computers are often printed on paper. Education, government, and industry could not operate without printing and writing papers. Other important paper products include paperboard, which is used in packaging, and absorbent papers, such as tissue and toweling.

World production of paper and paperboard totals more than 350 million tons (315 million metric tons) each year. The United States is the leading paper-producing country. Mills in the United States make about 30 percent of the world's paper and paperboard.

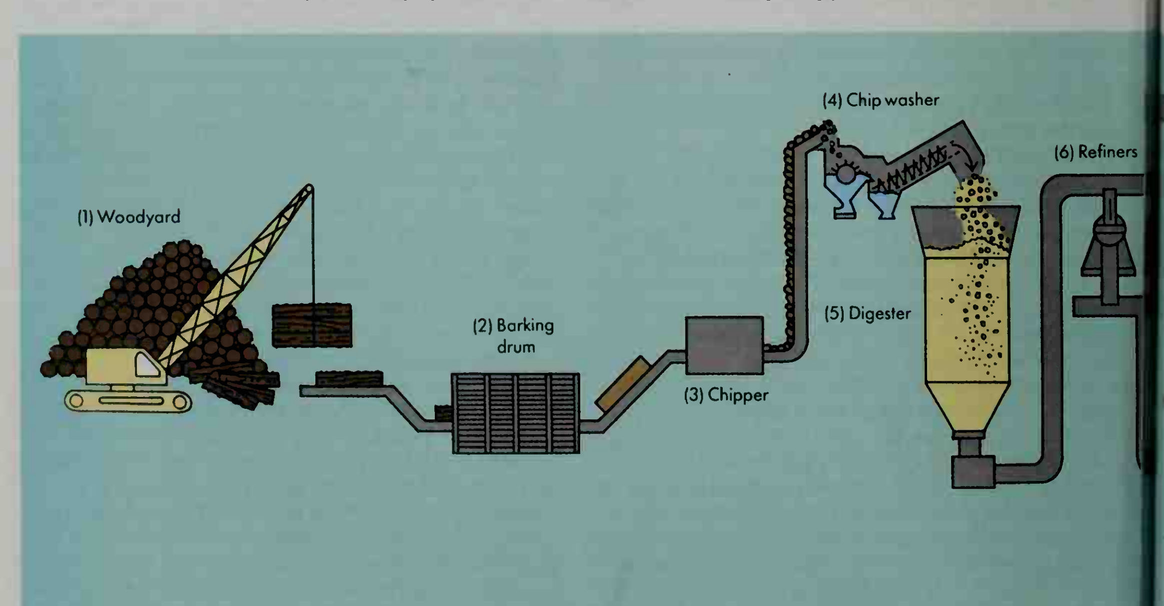
Paper is made from cellulose fibers, which are found in all plant cell walls. When a mixture of water and fibers is filtered through a fine screen, the fibers tangle together to form a sheet of paper. As the wet sheet is dried, chemical bonds form between the molecules in cellulose fibers next to one another, giving the sheet of paper its strength. Papermaking fibers come from many different plant sources, including bamboo, cotton, esparto, hemp, jute, sugar cane, wheat and rice straws, and various woods. Wood is the major source of papermaking fibers in North America.

Paper manufacturers produce thousands of grades and types of paper. The properties of any paper depend on the fibers and processes used in making it.

How paper is made

Raw materials. For centuries, the principal raw materials used in papermaking were cotton and linen fibers obtained from rags. Today, these fibers have been largely replaced by wood *pulp.* Pulp is the name used for fibers that have been prepared for papermaking. Wood used for papermaking is either harvested for this purpose or comes from lumber and woodworking wastes. Some cotton and linen fibers are still used for high-quality writing papers, business letterhead papers, art papers, and documents that will be kept for years.

Wood pulps are obtained from many kinds of wood, including aspen, beech, birch, fir, gum, hemlock, oak, pine, and spruce. The fibers used for papermaking were once living cells in the wood of the tree trunk. Fibers are thin, hollow tubes sealed at the ends, and are from $\frac{1}{25}$ to $\frac{1}{5}$ inch (1 to 5 millimeters) long. A substance called *lignin* holds the fibers together.



Waste paper is sometimes recycled to make new paper. Large tanks called *pulpers* convert newspapers, magazines, and other printed wastes into usable pulp. Ink is removed through use of solvents and other chemicals, detergents, and special cleaning methods. Recycled fiber is sometimes called *secondary fiber.* Manufacturers use secondary fiber to make paperboard, some printed papers, paper napkins, and toweling.

Pulping processes. There are three different kinds of pulping processes used to convert wood into pulp. They are (1) mechanical processes, (2) chemical processes, and (3) semichemical processes. Semichemical processes combine chemical and mechanical methods.

The oldest mechanical process is the *stone groundwood process,* in which short logs are forced against a specially prepared grindstone. Friction heats the wood and causes the lignin between the fibers to soften. The grindstone then can easily grind fibers from the wood's

How paper is made from wood

This diagram illustrates the steps involved in making paper from wood. It shows the semichemical method of making wood pulp. The pulping process begins with logs from the *woodyard.* The logs are fed into a revolving *barking drum,* which removes the bark. Then they are cut into chips in a *chipper.* The chips are washed in a *chip washer* and treated in huge tanks called *digesters.* In a machine called a *refiner,* rotating disks break the pulp down into individual fibers. The refined pulp passes into *pulp washers* where chemicals from the digesting process are rinsed off.

surface. In *thermo-mechanical pulping,* wood chips are preheated and fed between the rapidly rotating disks of a machine called a *refiner.* The mechanical action of the disks breaks the heated wood into individual fibers.

In chemical pulping processes, chemicals dissolve the lignin between the wood fibers. First, the wood is washed and cut into chips $\frac{1}{2}$ to 1 inch (12.5 to 25 millimeters) long. In the *sulfite chemical process,* the wood chips are cooked in an acid solution in a steam-heated pressure tank called a *digester.* In the *Kraft process,* also called the *sulfate process,* chips are cooked in a solution of caustic soda and sodium sulfide. The cooking can be done in a *batch digester* or in a large tower called a *continuous digester.*

Semichemical processes use chemicals to soften the lignin. Disk refiners then mechanically separate the fibers from one another.

Pulps produced by any of the processes are washed and then passed through a series of screens to remove knots, debris, and other foreign material. Some pulps may be bleached to produce a whiter sheet of paper.

Refining. In refining, the pulp passes between the rotating plates of a disk refiner. The mechanical action of the refiner unravels the fiber cell wall, making the fibers more flexible. The amount of refining the pulp receives determines the quality of the paper.

Sheet formation. At one time, all paper was made by hand, one sheet at a time. Today, a papermaking machine can make a continuous sheet of paper up to 33 feet (10 meters) wide, at speeds faster than 5,600 feet (1,700 meters) per minute. Some papermaking machines are more than 350 feet (110 meters) long. Among the most common machines are *Fourdrinier papermaking machines.*

In a Fourdrinier machine, a device called a *headbox* spreads a mixture of water and fibers across the *wire,* a continuously moving plastic screen. As the wire moves

The pulp is then forced through screens that remove knots, debris, and other unwanted material. The formation of paper sheets begins in the *headbox,* where wet fibers are spread across a moving plastic screen called a *wire.* Water drains off, leaving a mat of fibers. The mat passes between rollers that squeeze out most of the water. Steam-heated cylinders further dry it. The dried sheet is smoothed between the cylinders of a *calender stack* and fed onto a giant roll on a *paper reel.* Finally, the large roll of paper is shipped to a manufacturing plant to be made into finished products.

WORLD BOOK diagram by Arthur Grebetz

along the Fourdrinier machine, water drains off, leaving a mat of fibers on the surface of the wire. Suction devices help to drain the water through the wire. When the mat is about one-fifth fiber and four-fifths water, the sheet has enough strength to be removed from the wire. The sheet then passes between large press rolls that squeeze water from the sheet until it is about one-half fiber and one-half water. Most of the remaining water is removed as the sheet passes over steam-heated cylinders. Chemical bonds that hold the finished sheet together form during this drying process.

The dried sheet may be smoothed by pressing it between the cylinders of a *calender stack.* It is then wound into giant rolls at the *reel,* and shipped to manufacturing plants to be made into finished products.

Twin-wire machines are similar to Fourdrinier machines, except that the sheet is formed between two moving screens. This enables the papermaker to remove water from both sides of the sheet.

A *cylinder machine* is used to make heavy paper and paperboard. A wire-covered cylinder, called a *mold,* is partially immersed and rotated in a vat of water and fibers. The sheet forms on the cylinder as water passes through the screen covering. The wet sheet is removed from the mold by a moving fabric belt called a *felt.* Several sheets of fibers can be layered on a single felt to form a multilayer paperboard. Sheets formed on cylinder machines are pressed and dried before they are wound at a reel.

Special kinds of paper

The properties of paper depend on various factors. These factors include the type of pulp used, the amount of refining done on the pulp, and the kind of papermaking machine used. Special additives, as well as treatments given to the paper during or after its manufacture, also affect the finished product.

Newsprint is usually made from thermo-mechanical pulp, or from a blend of one part chemical pulp for strength and three parts groundwood pulp, for low cost and good printing properties. Many writing and printing papers are *sized* to prevent inks from spreading into the paper. Sizing is done either by including certain chemicals in the sheet or by coating the surface of the sheet with a starch solution. Dyes that bind to the pulp fibers produce colored papers. Many magazine and book papers are coated with a mixture of starch solution and clay. The coating becomes glossy when the paper is polished between the rolls of a *super-calender.* Paper treated in this way is especially good for printing.

Inexpensive writing papers are made from mechanical pulps. Higher-quality writing papers use blends of bleached chemical pulps. Rag pulps produce the finest writing papers. Many writing and document papers are *watermarked* by pressing a wire pattern into the top surface of the wet sheet while it is still on the Fourdrinier wire (see **Watermark**).

Toweling and napkins are made from recycled fibers or from blends of sulfite and mechanical pulps. Papermakers use special additives to give these products strength when wet. Most bag papers are made from well-refined, unbleached Kraft pulps. Bleached Kraft pulps are used for food packaging. Bleached Kraft paperboard may be coated with wax or plastic for milk cartons and paper cups. Cereal boxes and other cartons, tablet backs, and posterboards are made on cylinder machines from recycled newsprint.

Other products

Pulping processes produce a number of useful byproducts. For example, used Kraft pulping chemicals can be treated to recover turpentine and *tall oil,* a raw material used in paints and plastics. Imitation vanilla extract and alcohol can be made from used sulfite cooking solutions.

Some wood pulps are made for purposes other than papermaking. For example, mechanical and sulfite pulps serve as absorbent wadding in sanitary products and diapers. Manufacturers use pure sulfite pulps as raw materials for rayon and cellophane.

History

Paper gets its name from *papyrus,* a reed that the ancient Egyptians used for making a writing material. The Egyptians cut papyrus stalks into thin strips and pressed crisscrossed layers of strips into sheets.

Paper as we know it was invented in China about 2,000 years ago. At first, the Chinese used the hemp

A papermaking machine was the first device that could produce paper in a continuous roll rather than in single sheets. Nicholas Louis Robert invented the machine in 1798.

plant or the inner bark of the mulberry tree for fiber. Later, they found that good papermaking fibers could be obtained by pounding rags, rope, or fishing nets into a pulp. Early Chinese paper was too coarse for use in writing. The Chinese used it for wrapping and clothing.

The Chinese art of papermaking spread to other parts of the world after several Chinese papermakers were captured by Arabs in what is now Western Turkestan. The Arabs urged the papermakers to continue their art and teach it to the Moors in the city of Samarqand. The paper industry was established in Baghdad in A.D. 795. Papermaking spread to Europe as a result of the Crusades and the Moorish conquest of northern Africa and Spain. The first papermill in America was established near Philadelphia in 1690.

In 1798, a Frenchman named Nicholas Louis Robert invented a machine to make paper in continuous rolls rather than sheets. The Fourdrinier brothers, who were English merchants, financed improvements in this machine in 1803. The first American Fourdrinier machine was built in 1827.

The stone groundwood method for making wood pulp was developed in Germany in 1840. In 1854, the first chemically produced wood pulp was made in England. During the 1850's, the American chemist Benjamin C. Tilghman found that the fibers in wood could be separated by treating them with sulfurous acid. By 1882, much of the wood pulp used was made by this process.

In 1883, a German inventor named Carl Dahl discovered that adding sodium sulfate to the soda process produced a very strong pulp. This discovery produced the Kraft process. *Kraft* means *strength* in German. During the early 1900's, the Kraft process became the most important pulping process, and the Fourdrinier machine became the primary device for making paper.

Significant improvements in papermaking in recent years include thermo-mechanical pulping, synthetic wires and felts, twin-wire machines, and the use of computers to control pulping and papermaking operations. Paper manufacturers have also worked to improve pollution control and energy conservation in the industry.

Paper bag is one of our most useful items. It may vary in size from a small candy wrapper to a huge shopping bag. Yet, about a hundred years ago, the paper bag was unknown. In the 1850's, manufacturers shipped most commodities such as flour and sugar to storekeepers in bulk. If the customer did not bring a container, a clerk would make a *cornucopia,* or a twist from paper. As trade developed, many merchants began pasting such containers together in advance. They turned up the end to form a "package" ready for quick use. Several machines for making paper bags were invented in the United States by the early 1860's. S. E. Pettee built the best known of these machines. He began licensing his apparatus to printers in 1865. He collected a royalty for their use. Pettee's success spurred other inventors to creative effort, but these early attempts did not create the industry. The paper bag industry was born in 1869 when the best features of all types of machinery were purchased and put together in one machine by the Union Company of Pennsylvania.

The swift success of the concerns that started paper bag manufacture caused the Union Company to go into business itself in 1875 as the Union Bag and Paper Company. In the first year it made 606 million bags. This was a fabulous number in those days, and the industry was established. The mass production greatly cut costs to retailers.

Today, manufacturers produce four main types of paper bags: The *flat bag* is a flat tube sealed at one end, such as a small candy bag. The *square bag* has tucks at the sides to give more space. A popcorn bag is an example. The *satchel-bottom bag* has a large bottom section so that it will stand upright when filled. The *automatic bag* has a rectangle-shaped bottom and tucks in the side, so it can be opened easily with a snap of the hand.

Specialty bags include bags with slick linings to prevent snagging fragile items. Others may be greaseproof, mothproof, or heat-sealed. Larry L. Graham

Paperwork refers to the use of decorative papers. People have designed and used such papers for hundreds of years. Most decorative papers are made with paper produced by machines. But some of the finest decorative papers are made with handmade paper. The printing of decorative papers involves the use of such graphic arts processes as wood-block and linoleum-block engraving. Decorative papers can be divided into several categories, including end paper, lining paper, wallpaper, wrapping paper, and paper handicrafts.

End papers are decorative papers that printers once pasted on the inside of the front and back covers of books. The use of end papers dates back to early printed books. Most end papers were made of *marbled paper*—that is, paper printed to resemble the lined and mottled appearance of marble.

Lining papers are used to line drawers and to cover cupboards and shelves. They often have lively floral designs with a recurrent bird pattern. Lining papers may also be decorated with small, repeated landscapes.

Wallpaper is decorative paper used to cover inside walls. People have used wallpaper for hundreds of years in such countries as England, France, and the United States. During the 1700's, artists designed wallpaper with formal landscape scenes. Such paper was made only for the wealthy. It was widely used in France and England and exported to the United States. Also during the 1700's, many people used wallpaper decorated with Chinese objects and patterns, in a style called *Chinoiserie.* See **Wallpaper.**

Wrapping paper is used for wrapping gifts. Many wrapping papers have attractive and colorful patterns that make them suitable for use at holidays, birthdays, or other special occasions. The most common wrapping papers are glazed papers printed on one side only. Wrapping papers also include patterned tissue paper. In addition, people wrap gifts with such paperlike materials as metal foil and tinted cellophane.

Paper handicrafts have been popular in the United States since the 1600's. Today, people frequently make paper decorations and favors for parties and other special events. Crepe paper is widely used to make such objects as costumes, paper flowers, and holiday novelties, including Christmas tree ornaments. In the folk art called *quilling,* thin strips of paper are coiled and pinched into teardrop or eye shapes and glued together to make abstract designs and figures. Both the Chinese and the Japanese have developed traditional paper handicrafts that involve making cuts in folded pieces of paper. The cuts create elaborate patterns that appear when the paper is unfolded. The Japanese also fold uncut sheets of paper to make objects in an art form called *origami* (see **Origami**). Robert J. Lang

Papier-mâché, *PAY puhr muh SHAY,* is a mixture of paper and glue used in crafts and the fine arts. Papier-mâché is used to make such items as furniture, jewelry, masks, dolls, and toys. Artists use papier-mâché to create sculptures.

Traditional papier-mâché involves tearing paper into small pieces and adding them to white glue or wallpaper paste until the mixture becomes pasty. The mixture can be placed into a mold or built up on a frame made of wire or other material. The frame has the skeletal shape of the object being made. Papier-mâché can also be made by tearing paper into small squares and coating each piece with glue. The pieces can be pasted on cardboard, metal, wood, or other surfaces to cover and decorate objects.

After papier-mâché has dried and hardened, its surface can be smoothed with sandpaper and painted. Lace, string, and other decorations can also be added. Papier-mâché can also be coated with varnish or other substances to make it water-resistant and durable.

Papier-mâché was probably developed by the Chinese during ancient times. In the 1600's, the French became the first Europeans to use papier-mâché, creating boxes, trays, and other decorative objects. The English became noted for the beautiful furniture they made with the material during the 1800's. Dona Z. Meilach

Papineau, *PAHP un noh* or *pa pee NOH,* **Louis Joseph** (1786-1871), organized a French-Canadian revolt against the government of Lower Canada in 1837. The rebellion failed, but it focused attention on the desire of French Canadians to control their own affairs.

Papineau was born in Montreal. In 1809, he won election to Lower Canada's legislature. French Canadians formed a majority in the elected assembly. But the British governor and an appointed Legislative Council controlled by English-speaking officials decided all important matters. Papineau's group, called the Patriots, tried to lessen the influence of the Council. Their inability to do so led to the rebellion in November 1837. Papineau fled to the United States to avoid arrest and later moved to Paris. He returned to Canada in 1845, when the government granted him a pardon. Papineau served in the Canadian legislature from 1848 to 1854. Fernand Ouellet

Papua New Guinea, *PAH poo ah nyoo GIHN ee,* is an independent nation in the Pacific Ocean, north of Australia. It consists of part of the island of New Guinea plus a chain of tropical islands that extend more than 1,000 miles (1,600 kilometers).

The eastern half of New Guinea makes up most of Papua New Guinea's area. The country also includes the islands of the Bismarck Archipelago, Bougainville and Buka in the Solomon Islands chain, the D'Entrecasteaux Islands, the Louisiade Archipelago, the Trobriand Islands, and Woodlark Island. Port Moresby, on New Guinea, is Papua New Guinea's capital and largest city.

The islands that make up Papua New Guinea were Australian territories during much of the 1900's. Papua New Guinea gained its independence in 1975.

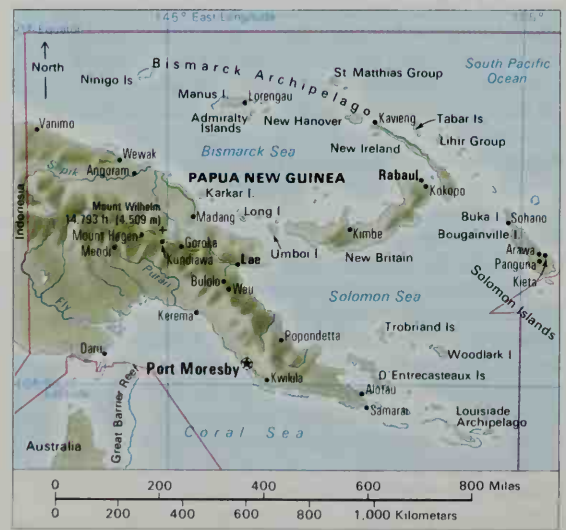
monarchy. The British monarch serves as head of state and is represented on the islands by a governor general. The people elect a national legislature, which elects a prime minister to head the government.

People. About 98 percent of the population of Papua New Guinea are Melanesians. Most of the people live in small rural villages. About 40 percent of the population live in valleys in the country's interior highlands. Most of the people are Christians.

The people of Papua New Guinea speak about 850 languages. To communicate with one another, the people use widely understood languages called *lingua francas.* These languages include Pidgin English (Tok Pisin) and Police Motu. About three-fourths of the people 15 years of age and older can read and write. For the literacy rate, see **Literacy** (table: Literacy rates). More than 80 percent of primary-school age children attend school, but only about 15 percent of secondary-school age children do so.



Land and climate. Papua New Guinea's larger islands—including New Guinea, New Britain, and Bougainville—have many high mountain ranges. Volcanoes are common on the northern coasts. Thick tropical forests cover about 80 percent of these islands. Swamps cover much of the coastal land. The country's outlying small islands are the tops of underwater mountains. Many of them are fringed with coral. Papua New Guinea has a hot, humid climate. The temperature averages from 75 to 82 °F (24 to 28 °C) in the lowlands and about 68 °F (20 °C) in the highlands. An average of about 80 inches (203 centimeters) of rain falls annually.

Economy of Papua New Guinea is based largely on agriculture. Most of the people raise crops. They grow most of their own food, including sweet potatoes, yams, and cassava and taro plants. They also produce products that they sell, including cocoa, coconuts, coffee, palm oil, rubber, and tea. Copper, gold, and petroleum are

the most valuable exports. Gold and copper are mined at Ok Tedi near Papua New Guinea's border with Indonesia. Gold mines also operate at Porgera in the New Guinea central highlands and on the island of Lihir.

Road construction is difficult in Papua New Guinea. Many parts of the country can be reached only by air, foot, or canoe. A national airline operates among the islands. The country has about 15 radio stations, 2 daily newspapers, and 1 commercial television station.

History. People lived in what is now Papua New Guinea at least 50,000 years ago. Farming began there more than 9,000 years ago. The people developed rich traditions of pottery, carving, dance, body decoration, and sea navigation. In the early 1500's, Spanish and Portuguese explorers landed on the islands. The Dutch and English visited the islands during the next 300 years.

In 1884, Germany annexed northeastern New Guinea and the islands off its shore. That same year, the United Kingdom took over southeastern New Guinea and the nearby islands. In 1906, Australia took over administration of the British territory and named it the Territory of Papua. In 1914, during World War I, Australia seized the areas held by Germany. In 1920, the League of Nations officially put these areas under Australian control. Japanese forces invaded the islands in 1942, during World War II. They held much of New Guinea and several of the other islands. After the war ended in 1945, Australia placed northeastern and southeastern New Guinea, along with the nearby islands, under one government.

The islands gained independence as Papua New Guinea on Sept. 16, 1975. In 1988, conflicts over mining and land rights began on Bougainville. The attacks soon grew into a rebellion seeking that island's independence. The government and rebel leaders signed a ceasefire in 1998 and a peace agreement in 2001. Under the peace accord's terms, Papua New Guinea has agreed to grant Bougainville greater *autonomy* (self-rule). The accord also authorizes a referendum to eventually be held on the question of independence. Hank Nelson

Papyrus, *puh PY ruhs,* is a water plant whose fibers were used by the people of ancient Egypt to make a writing material. It served also as a material for mats, sandals, and sailcloth for light skiffs. The brownish flowers were made into garlands for the shrines of the Egyptian gods. Many people think the mother of Moses hid her son in an ark made of papyrus.

The papyrus plant still grows in the Nile Valley of Egypt. It is also found in Ethiopia, Syria, southern Italy, and Sicily. The plant's reedlike stems grow 3 to 10 feet (0.9 to 3 meters) high. As many as 100 flower stalks spring from the top of each stem. These stalks may be more than 12 inches (30 centimeters) long. Coarse *bracts* (leaflike structures) surround the cluster of stalks. The flowers grow in clusters at the ends of the stalks.

The Egyptians made a writing material, also called *papyrus,* by laying strips of the plant's stem in layers, and placing them under pressure. The crushed strips matted into a loose-textured, porous, white paper. Time has turned surviving papyrus manuscripts brown and brittle. The paper was sold as long, rectangular sheets of differ-

Parable, *PAR uh buhl,* is a brief story, proverb, or saying that expresses a moral. Most parables illustrate difficult or mysterious ideas through situations that can be easily understood. Almost all parables express religious ideas, and the Bible includes many such stories. For example, the Old Testament contains a parable told by Nathan to King David. A rich man had many sheep, but a poor man had only one. The rich man wanted to feed a traveler who called at his door. To do so, he killed the poor man's only sheep, rather than kill one of his own. Nathan was actually comparing the rich man with David, who had married another man's wife (II Sam. 12:1-7).

The best-known parables are those of Jesus Christ in the New Testament. Jesus used simple, everyday situations to express such ideas as the Kingdom of God, the proper use of wealth, and the nature of prayer. For example, he compared Judgment Day to a fisherman's net cast into the sea (Matt. 13:47-50). The net caught all kinds of fish. But after it was pulled to shore, the edible fish were kept and the bad-tasting ones were thrown away. Jesus was saying that on Judgment Day, people who have been saved from damnation will likewise be separated from the damned. Mark E. Workman

Parabola, *puh RAB uh luh,* is one of the curves most used in science. If a ballplayer hits a high fly, the path of the ball is nearly a parabola. Any point on a parabola is equidistant from a line *AB* and point *C.* Line *AB* is the *directrix* and point *C* is the *focus.* The solid line through point *C,* which bisects the parabola, is called the *axis.*

A parabola revolved about its axis generates a *parabolic surface.* A light at the focus of a mirror with this shape would cause the light rays that hit the mirror to reflect parallel to the axis. Scientists use this principle

Paracelsus, *PAIR uh SEHL suhs,* **Philippus Aureolus,** *fih LIHP uhs aw REE oh luhs* (1493?-1541), was a Swiss physician who introduced the use of drugs made from minerals. His drugs included such minerals as sulfur, mercury, and antimony. Paracelsus challenged the ancient Greek and Roman belief that disease is caused by an imbalance of body *humors* (fluids). He argued that each illness has a specific, external cause.

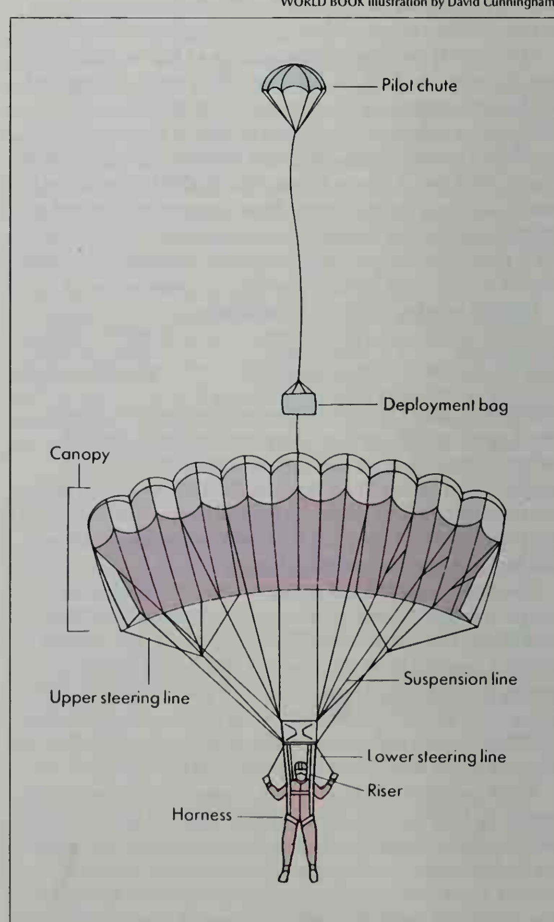
Paracelsus was the first physician to treat disease with moderate doses of minerals that had been *detoxified*—that is, they had their poisons removed. He also became the first physician to correctly describe chorea, silicosis, congenital syphilis, and tuberculosis.

Many of Paracelsus' theories were criticized, however, because they were based in part on unscientific principles associated with alchemy, astrology, and mysticism (see **Alchemy**). Paracelsus argued that disease is caused by external factors that take possession of part of the body. But he also believed that spiritual forces were among the causes of disease and that he, as a spiritualist, could control them with the use of minerals and herbs.

Paracelsus was born at Einsiedeln, Switzerland. His given and family name was Theophrastus Bombastus von Hohenheim. He received his early education from his father, a physician. John Scarborough

Parachute is a device used to slow the fall of a person or object from an aircraft or any other great height. The operation of a parachute is based on simple principles. There are two forces that act on any falling object—gravity and air resistance. Gravity pulls the object toward the earth. But air resists the object's movement. Because the pull of gravity is much stronger than the resistance of the air, the air can only slow the speed of the falling object. Large surfaces offer the greatest resistance to the air. Thus, the larger the parachute's surface, the more air resistance it meets and the slower it falls.

Uses of parachutes. One of the early uses of parachutes was to allow descent from gas-filled balloons. Since the development of airplanes, parachutes have been used for emergency jumps from damaged aircraft. They have also been used to deliver cargo. Airplanes drop food and medicine by parachute to places that cannot be reached easily by other means. Special military uses for parachutes were developed during the 1930's. Both the Allies and Germans used *paratroops,* or parachute troops, during World War II (1939-1945). Some airplanes use parachutes as brakes when landing. Parachutes are also used to recover the booster rockets from spacecraft that have been launched into the atmosphere. Today, most parachutes are used for sport jumping, called *skydiving.*



Parts of a parachute. The part of the parachute that catches the air is called the *canopy.* For many years, parachutes had a round canopy that looked somewhat like an umbrella. Today, most canopies have a rectangular shape, somewhat like the wing of an airplane. The front part of a rectangular canopy is cut off, allowing air to enter. The air inflates the canopy and makes it fairly rigid, like an air mattress.

Skydivers generally use a rectangular parachute that is twice as wide as it is deep. Many sport parachutes measure 11 by 22 feet (3.4 by 6.8 meters). Round parachutes, which are used mainly for cargo, may measure up to 100 feet (30 meters) across. Parachute canopies

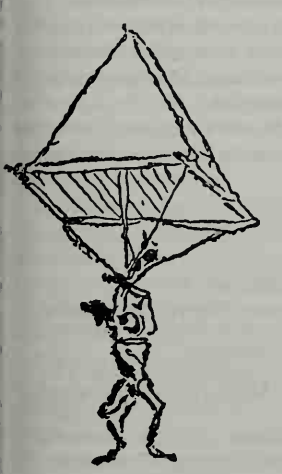
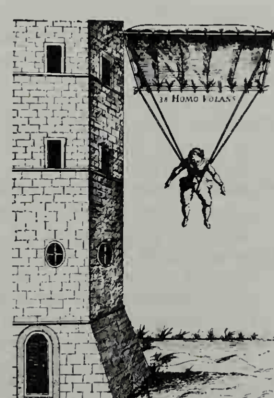
were once made of silk. But nylon, which is stronger and cheaper, has been used since the early 1940's.



The canopy is packed in a container made of heavy nylon cloth. Special pins called *ripcord pins* hold the container shut. The container is attached to the parachutist's body by a *harness* that fits around the shoulders and legs. Straps called *risers* connect the harness to *suspension lines,* which attach to the canopy. Skydivers wear a main parachute and a reserve parachute for emergencies. The reserve parachute is usually mounted on the back, just above the main parachute.

How parachutes work. Skydivers generally open their parachutes at about 2,500 feet (750 meters). The parachutist reaches into a pouch on the leg strap and pulls out a pilot parachute that measures about 3 feet (0.9 meter) across. This parachute quickly inflates, releases the ripcord pin on the container, and pulls out the canopy. If the main parachute fails, there is time to activate the reserve parachute. After the canopy opens, the ride to the ground takes about 3 minutes. The parachute moves at about 20 miles (32 kilometers) per hour. The parachutist can pull on the right steering line to turn right and on the left steering line to turn left.



Rectangular parachutes have a greater forward speed than round parachutes and so are not easily blown backward when they encounter wind. Rectangular parachutes also descend more slowly than round parachutes. In landing, the parachutist can pull down the back edge of the rectangular canopy with steering lines. This slows the parachute's motion and permits a gradual, soft landing.

History. As early as the 1100's, the Chinese may have experimented with parachutes by jumping from high structures with rigid, umbrellalike devices. The first known parachute jump was made from a tower in 1783 by the French physicist Sebastian Lenormand. The first parachute jump from a balloon was made in 1797, and the first freefall parachute jump from a damaged airplane in 1922. Dan Poynter

Parade is a public march or procession honoring a particular occasion. The mood of a parade may vary from joyous excitement to solemn dignity. Members of the armed forces often parade on holidays to show off their strength, condition, equipment, and skill. Many parades have floats, music, marchers, and trained animals.

Parades in the form of religious processions go back to about 3000 B.C. Ancient cities often had special, elaborately constructed streets whose main function was to provide a place for processions. The Romans enjoyed parades, especially the processions of the performers at the circus. They also had frequent military parades, called *triumphs,* during the time of the empire (see **Triumph**). Parades to honor particular feasts became popular in the early Christian church, and remain so today. Political parades were especially popular in the United States in the 1880's and 1890's.

Paradise is a name for heaven. It was originally a Persian word used for the amusement parks of Persian kings. The Greeks borrowed the word from the Persians. Greek translators of the Bible used the word paradise in reference to the Garden of Eden (Gen. 2-3). Jewish authors after 200 B.C. saw paradise as a place of reward after death. Early Christian writers used the term in the same sense. For example, in the Gospel of Luke, Jesus is reported as promising paradise to a thief dying on the cross. See also **Heaven**. Joseph M. Paraffin, *PAR uh fihn,* is a commonly used term for *paraffin wax,* a white, partly clear material. Paraffin wax forms a moisture-proof film, and is used to make waterproof cardboard containers such as milk cartons. It is also the major ingredient in candles.

The wax is made up of a mixture of substances known by the chemical term *paraffin.* A paraffin is a type of *hydrocarbon* (a substance containing hydrogen and carbon). See **Hydrocarbon**. Paraffin wax comes from *petroleum fractions* (products separated from petroleum). Chilling the fractions and pressing them through a filter removes heavy oil. The remaining solid is paraffin wax.

Ordinary paraffin wax melts at 90 °F to 150 °F (32 °C to 66 °C). *Microcrystalline wax,* which is composed of larger hydrocarbons, melts at 150 °F to 185 °F (66 °C to 85 °C). Geoffrey E. Dolbear

Paragraph is a section of a written work that consists of one or more sentences constructed and arranged to function as a unit. The first line is normally indented. The subject or topic of a paragraph is often stated in the first sentence, called a *topic sentence.* Paragraphs may range in length from a single word used for emphasis, such as "Never!," to several hundred words. However, most paragraphs are from 100 to 200 words long.

An effective paragraph must be unified, ordered, and complete. A paragraph is unified when all the sentences contribute to creating a single idea. A paragraph has order when the sentences form a pattern, such as leading from cause to effect or from the particular to the general. A paragraph is complete when the writer brings its idea clearly into focus. William E. Coles, Jr.

Paraguay

Paraguay, *PAIR uh GWAY* or *PAIR uh GWY,* is a small landlocked country near the center of South America. It is surrounded by Argentina, Bolivia, and Brazil. The Paraguay River flows through Paraguay from north to south and divides the country into two sharply different land regions. West of the river lies the Chaco, a flat, thinly settled area of coarse grasses, scrub forests, and salt marshes. Eastern Paraguay, on the other hand, has rolling hills, fertile soil, and thick forests.

The great majority of the Paraguayan people live in the eastern part of the country. About a fifth of them live in or near Asunción, the capital and largest city. Almost all Paraguayans are of mixed Guaraní Indian and Spanish ancestry. The Guaraní Indians were the original inhabitants of what is now Paraguay. They intermarried with Spanish settlers, who began to arrive in the 1500's. Most Paraguayans speak both Guaraní and Spanish. Nearly all the people are Roman Catholics.

Paraguay is a poor country whose economy is based chiefly on agriculture and forestry. About half the people of Paraguay live in rural areas, and most of them make a bare living farming. The country's most valuable resources are fertile soil, dense forests, and vast hydroelectric power potential. These resources could provide for strong economic growth in Paraguay if they were more developed.

Spain ruled Paraguay until 1811, when Paraguay declared its independence. Over the years, the country has suffered from terrible wars with neighboring nations and from struggles for power among rival political groups.

Government

National government. Paraguay's Constitution, adopted in 1992, provides for a democratic form of government. Under the Constitution, voters elect the president, Paraguay's head of government, to a five-year term. The president may not be reelected.

The president appoints a cabinet called the Council of Ministers. The cabinet members head the government

departments and assist the president in carrying out the operations of Paraguay's government.

Paraguay's legislature, called the National Congress, consists of a 45-member Senate and an 80-member Chamber of Deputies. Voters elect the members to five-year terms.

Local government. Paraguay is divided into 17 departments for the purposes of local government. Voters elect a governor to be the head of each department. The departments are subdivided into smaller units of government.

Politics. The National Republican Association, popularly called the Colorado Party, is Paraguay's largest single political party. It dominated the country's politics from 1947 to 1993, when the first democratic, multiparty elections were held. The Democratic Alliance, a coalition of political parties, forms the main opposition to the Colorado Party. The law requires all citizens of Paraguay 18 years of age and older to vote.

Courts. The Supreme Court Justice is Paraguay's highest court. It has nine justices. The justices are appointed by the Senate from candidates that are proposed by a council of government representatives, lawyers, and law professors. The Supreme Court justices serve until age 75.

Armed forces. Paraguay's armed forces have about 20,000 men. Men are drafted at age 18 and serve one year in the country's army or air force, or two years in the navy.

People

Population and ancestry. More than 95 percent of Paraguay's people live in the eastern part of the country. The rest live in the west, or the Chaco, where poor soil, an arid climate, and a lack of roads have discouraged settlement.

The Guaraní Indians lived in what is now Paraguay long before the first Spanish settlers arrived in the 1500's. Over the years, a large number of Indians and Spaniards intermarried. Today, about 95 percent of all Paraguayans are *mestizos* (persons of mixed white and Indian ancestry). A small number of people of unmixed Indian ancestry live in the Chaco. People of Chinese, German, Korean, and Japanese descent also make up minorities in Paraguay.

Languages. Paraguay has two official languages—Spanish and Guaraní. Spanish is used in the schools, in government, and in commerce. But people throughout Paraguay generally use Guaraní in everyday conversation. Books, newspapers, and magazines are published in both languages.

Way of life. Paraguay has a large lower class, which consists of nearly all rural people and most city dwellers. Middle-class Paraguayans, most of whom live in urban areas, form a small but growing portion of the population. The nation's tiny upper class consists chiefly of government officials, military leaders, and wealthy landowners and business people.

Rural life. Most Paraguayans who live in rural areas are farmers who grow food mainly for their own families. Other rural Paraguayans work on cattle ranches, on large farms that produce crops for export, in forestry, or in small factories that process farm or forest products.

Most rural Paraguayans live in one-room houses

Symbols of Paraguay. Paraguay's flag has the coat of arms on the front, *left,* and the Treasury seal on the back. It is the only national flag with a different design on each side. The star on the coat of arms, *right,* stands for independence from Spain.

called *ranchos.* A typical rancho has a dirt floor; reed, wood, or brick walls; and a thatch roof sloped to carry off heavy rains. A separate or attached shed serves as a kitchen. Few houses have indoor plumbing.

City life. About half of the people of Paraguay live in cities and towns. Asunción, the capital, is the largest city by far. It has about half a million people. Other major cities include Ciudad del Este, Fernando de la Mora, Lambaré, and San Lorenzo. City dwellers include craftworkers, unskilled laborers, factory workers, government employees, office workers, shopkeepers, and professional people. In general, urban Paraguayans have a higher standard of living than do the people in rural areas. The cities have better schools, more medical facilities and other services, and a variety of cultural and recreational activities.

Many city people live in small, pastel-colored houses made of brick or stucco. The houses have red tile roofs, and iron grillwork covers the windows. The poorest people live in shacks built of scraps of wood or metal. Unlike many other large Latin-American cities, Asunción does not have sprawling slum areas.

Clothing. Urban Paraguayans dress as people do in the United States and Canada. Many rural women wear a shawl, called a *rebozo,* and a simple dress or a skirt and blouse. Rural men generally wear loose trousers, called *bombachas,* a shirt or jacket, a neckerchief, and a poncho. Most rural Paraguayans go barefoot.

Food and drink. Paraguayans eat much meat, especially beef. Beef is often cooked with vegetables in a stew called *puchero.* Another common food is *cassava,* a starchy root vegetable. Cassava may be boiled or ground into flour and made into a kind of bread called *chipá. Sopa paraguaya,* often served on special occasions, consists of corn meal cooked with eggs, milk, onions, and cheese. The favorite beverage is a tea called *yerba maté* or simply *maté.* It is made from the leaves of a holly tree that grows in the eastern forests.

Recreation. Soccer is the favorite sport in Paraguay. The people also enjoy basketball, volleyball, horse racing, and swimming. Paraguayans celebrate religious holidays with festivals that often include music, dancing, parades, and athletic contests.

Religion. Over 90 percent of the Paraguayan people are Roman Catholics. The Constitution makes Catholicism the state religion, but it guarantees freedom of worship. Protestants, many of whom are Mennonites, make up about 1 percent of the population.

Education. Most Paraguayans over age 15 can read and write. For the country's literacy rate, see **Literacy** (table: Literacy rates). Paraguay's government provides free public schooling through the university level. The country also has many private schools, which charge tuition. The law requires children from the ages of 7 through 13 to attend school. But the law is not strictly enforced, especially in rural areas. Many rural children never attend school or drop out to help their families farm the land. In addition, numerous rural areas have teacher shortages, and some have no schools at all. Paraguay has two universities—the National University of Asunción and Catholic University. Catholic University operates in Asunción, Villarrica, Concepción, Encarnación, and Pedro Juan Caballero.

The arts. Various Paraguayan arts show the influence of the Guaraní Indian culture. Popular music, for example, has a slow rhythm and is played in a sad minor key typical of traditional Guaraní music. Artists commonly portray Guaraní culture in their paintings. Craftworkers use Guaraní designs in producing fine pottery and handwoven baskets. Paraguay's most famous handicraft, however, is *ñandutí* lace, made by the women of the town of Itauguá. *Ñandutí* means *spider web* in Guaraní. The complicated patterns of ñandutí lace represent flowers, animals, and other familiar objects.

Spanish missionaries, who began to arrive in Paraguay in the 1500's, developed a written form of the Guaraní language. However, Guaraní was not used in literary works until the 1900's, and Guaraní literature today is little known outside Paraguay. Many Paraguayan literary works written in Spanish deal with events in the country's history.

The land and climate

Land regions. The Paraguay River flows southward through Paraguay. It divides the country into two major regions: (1) the Chaco, officially called Occidental Paraguay, and (2) Eastern Paraguay, officially called Oriental Paraguay.

The Chaco stretches westward from the Paraguay River. It is part of the Gran Chaco, a large region that extends into Argentina and Bolivia. The Chaco occupies about three-fifths of Paraguay but has less than 5 percent of its population. Coarse grasses, scrub forests, and thorny shrubs cover much of the Chaco. The forests include quebracho trees. Quebrachos are a source of *tannin,* a chemical used to process leather.

Several slow-moving rivers flow through the southern and eastern Chaco. The Pilcomayo River forms Paraguay's southwestern border with Argentina. The Pilcomayo and other rivers in the Chaco often overflow after heavy rains in the summer. Some of the rivers disappear during the winter dry season, and salt marshes form. In

much of the Chaco, the underground water is too salty for drinking or irrigation. Cattle ranches occupy parts of the region, mainly in the south. German-speaking people of the Mennonite faith have established several farming communities in the central Chaco, and scattered tribes of Guaraní Indians live in remote parts of the region. But most of the Chaco is uninhabited.

Eastern Paraguay lies between the Paraguay River and the Paraná River. The Paraná forms part of Paraguay's border with Argentina and Brazil. The river flows through Argentina to the Atlantic Ocean. The Paraná thus provides Paraguay with an outlet to the sea. The heavily forested Paraná Plateau occupies the eastern third of the region. The rest of the region consists of low, grassy plains and forested hills.

More than 95 percent of all Paraguayans live in Eastern Paraguay. Most of them live along the Paraguay River or in the southwestern part of the region, where small towns and farming villages dot the rolling countryside. Asunción lies on the Paraguay River, near the point where it meets the Pilcomayo River.

Climate. Most of Paraguay has a warm, humid climate. The Chaco is the hottest and driest part of the country, and the Paraná Plateau is the coolest and wettest. Paraguay lies south of the equator, and so its seasons are opposite those in the Northern Hemisphere. Temperatures in Asunción average 65 °F (19 °C) in July and 84 °F (29 °C) in January.

Eastern Paraguay receives about 50 to 65 inches (127 to 166 centimeters) of rain annually. The rain falls throughout the year in the region. The Chaco receives about 20 to 40 inches (51 to 102 centimeters) of rain yearly. It often has winter droughts and summer floods.

Economy

Paraguay has a developing economy. Service industries and agriculture, including forestry, account for most of the nation's *gross domestic product* (GDP)—the total value of all goods and services produced in the country yearly. Many businesses and industries are pri-

vately owned. However, the national government plays a major role in economic planning and development. It also owns firms in such fields as banking, manufacturing, transportation, and energy production.

Service industries account for about 55 per cent of Paraguay's GDP and employ about 45 per cent of the work force. Many of the workers are employed by government agencies; stores, restaurants, and hotels; banks; health care facilities; and schools. Others work in such fields as transportation and communication.

Agriculture and forestry largely form the basis of Paraguay's economy. They account for about 30 per cent of the nation's GDP, and they employ about 45 per cent of all of Paraguay's workers. Large cattle ranches cover parts of the Chaco and much of Eastern Paraguay. Eastern Paraguay has the country's best soil. Farmers grow such crops as cassava, corn, cotton, rice, soybeans, sugar cane, and tobacco.

Farms occupy only about a fifth of the land that could be used in Paraguay to grow crops. One reason is that many farmers do not raise much more food than they need for their families. In addition, the use of old-fashioned tools and methods keeps farmers from cultivating as much land as could be farmed. Many farmers do not own or even rent their land. Instead, they are *squatters* on public or private land. They work small plots until the soil is no longer productive, then move on to another area. Since the mid-1900's, government programs have encouraged farmers to use modern tools and methods and to buy land in undeveloped areas.

Forests cover about half of Paraguay and rank among the country's most valuable natural resources. Many kinds of trees are cut for lumber. Quebracho trees, which grow mainly in the Chaco, are harvested for tannin, which is used to tan hides. Holly tree leaves are used to make yerba maté tea. Other valuable trees in Paraguay include cedars, coconut palms, and wild citrus trees.

Manufacturing accounts for about 15 per cent of Paraguay's GDP and employs about 10 per cent of its workers. The largest factories are in or near Asunción. Major manufactured goods include cement, leather goods, processed food and beverages, textiles, and wood products.

Energy sources. Hydroelectric power plants on the Acaray and Paraná rivers provide Paraguay with plentiful electricity. In addition, the country has enormous potential for further hydroelectric power development. The Itaipú Dam power plant, which was built by Paraguay and Brazil on the Paraná River, is one of the world's largest hydroelectric power projects. The plant began generating electricity in 1984 and was completed in 1991. Itaipú has the capacity to generate about $12\frac{1}{2}$ million kilowatts of electricity.

Trade. Paraguay's chief exports include coffee, cotton, lumber, meat products, soybeans and other oilseeds, tannin, tobacco, and vegetable oils. Its leading imports include chemicals, fuels and lubricants, iron and steel, machinery, and transportation equipment. Paraguay trades mainly with Argentina, Brazil, the United States, and western European countries.

Transportation and communication. Rivers serve as an important means of transportation in Paraguay. Asunción, the main port, lies on the Paraguay River about 1,000 miles (1,600 kilometers) from the Atlantic Ocean. To reach the ocean from Asunción, boats travel down the Paraguay to the Paraná River, which flows through Argentina and empties into the Atlantic. Paraguay's major cities are connected by paved highways, but less than a fifth of the country's roads are paved. Less than 2 per cent of all Paraguayans own an automobile. Friendship Bridge spans the Paraná River at the city of Cuidad del Este. It links the Paraguayan road system to a Brazilian highway that runs to the port of Paranaguá on the Atlantic coast. Paraguay's only major railroad carries passengers and freight between Asunción and Encarnación. An airport near Asunción handles international flights.

Paraguay has four daily newspapers. About 5 per cent of the people own a radio, and less than 3 per cent own

History

Early days. Guaraní Indians were the first people to live in what is now Paraguay. They were fairly peaceable people who grew corn and other crops, hunted game, fished, and gathered wild fruits. In the early 1500's, Spanish and Portuguese explorers became the first whites to reach Paraguay. They were searching for a route across the continent to Peru and its treasures of silver and gold. In 1537, a Spaniard named Juan de Ayolas traveled up the Paraná and Paraguay rivers to a point north of what is now Asunción. He then went inland across the Chaco region. The men he left behind built a fort at Asunción. Under the leadership of Domingo Martínez de Irala, the settlement of Asunción became the seat of government for all of Spain's colonies in southeastern South America.

The Jesuits. Missionaries of the Jesuit order began to arrive in Paraguay in 1588 to convert the Guaraní to Roman Catholicism. They organized mission settlements called *reducciones* or *reductions,* where the Indians lived and worked. The Jesuits taught the Guaraní such skills as weaving, carpentry, and printing. Most of the Indians farmed the land or tended cattle. In return, they received food, clothing, and other goods. The reducciones became prosperous settlements that exported cotton, tobacco, yerba maté, hides, and wood. By the 1730's, the Jesuits had built about 30 reducciones with a total population of about 140,000.

Many Spanish colonists came to envy the wealth and power of the Jesuits. They wanted to use the cheap Indian labor themselves on their farms. The Jesuits, on the other hand, felt they were protecting the Indians from possible slavery and formed armies to guard the reducciones. Complaints from the colonists about the Jesuits' power led the Spanish king, Charles III, to expel the Jesuits from all Spanish territory in 1767. The Jesuits left Paraguay, and the reducciones were abandoned. Some Indians returned to their old ways of life. Others worked on estates of the Spanish colonists.

Independence. Throughout the 1600's and 1700's, many Paraguayans felt that Spain neglected their colony, and they resented the taxes the mother country demanded. In 1776, Spain made Paraguay part of one large colony called the Viceroyalty of La Plata. Buenos Aires, Argentina, became the capital of the viceroyalty. Paraguayans disliked having to take orders from Buenos Aires. In 1811, they overthrew the Spanish governor in Asunción and declared their independence. They formed an assembly to rule their new nation.

In 1814, the assembly chose José Gaspar Rodríguez de Francia, a Paraguayan lawyer, to head the government. Two years later, the assembly made him dictator for life. Francia governed by military force. He distrusted foreigners, and so he prohibited immigration and forbade trade with other nations. Paraguay was isolated from the rest of the world, but it developed a strong sense of unity and independence.

Francia died in 1840. An assembly chose Carlos Antonio López to govern the country. In 1844, another assembly adopted a republican Constitution and named López president. Like Francia, López ruled as a dictator, but he

reversed Francia's policies. López encouraged trade and invited foreign technicians to settle in Paraguay. He also built roads and schools and created a powerful army.

Military ruin. López died in 1862. The Paraguayan legislature then elected his son Francisco Solano López president with dictatorial powers. López resented Paraguay's larger neighbors, Argentina and Brazil, and wanted to increase his country's influence in the region. In 1864, he went to war with Brazil. After Argentina refused to let Paraguayan troops cross its territory to attack Brazil, López declared war on Argentina. Argentina, Brazil, and Uruguay joined forces in 1865 and fought Paraguay in the War of the Triple Alliance, also called the Paraguayan War. The war lasted until 1870, when López was killed and Paraguay surrendered. The war left Paraguay in ruins. The population dropped from about 525,000 in 1865 to about 220,000 in 1871.

After the war, the country was plagued by struggles for power among rival political groups. More than 30 presidents headed the government of Paraguay from 1870 to 1932.

A dispute over ownership of the Chaco led Paraguay into war with Bolivia in 1932. Paraguay again suffered many casualties. The two nations signed a truce in 1935. A final settlement in 1938 gave Paraguay new territory in the Chaco.

Political unrest continued to trouble Paraguay after the Chaco War. A series of presidents again governed the country amid widespread complaints of low living standards, inadequate public services, and poor working conditions. Paraguay's economy improved during World War II (1939-1945). The United States provided loans and other aid to secure Paraguay's friendship. Paraguay declared war on Germany and Japan in 1945, but no Paraguayan troops fought in the war.

Civil war broke out in Paraguay in 1947 as rebels attempted to overthrow President Higinio Morínigo, who had ruled as dictator since 1940. The revolt was crushed. However, the Colorado Party, which had supported Morínigo, split into two groups. Morínigo was eventu-

ally forced to leave the country, and the rival Colorado groups fought for control of the government. Federico Chaves, the leader of one group, seized power in 1950. General Alfredo Stroessner, commander in chief of the armed forces and head of the other group, forced Chaves to resign in 1954. Stroessner ran as the Colorado candidate in elections later that year and was elected president without opposition.

Stroessner's rule and overthrow. Stroessner used military and police powers to keep control of the government and was reelected seven times between 1958 and 1988. The government imprisoned many of its opponents and sent others into exile. By maintaining political stability, Stroessner was able to attract foreign aid and investments and so begin a broad program of economic development. The government started projects to modernize agriculture, build roads, and promote new industries.

Through the years, a growing number of Paraguayans called for greater political and human rights. In 1989, Stroessner was overthrown during a coup led by General Andrés Rodríguez Pedotti, who became president.

Paraguay adopted a new constitution in June 1992, and the country has held regular democratic, multiparty elections since 1993. The Colorado Party's presidential candidate has won each of the elections.

In 1999, Vice President Luis María Argaña was assassinated. The National Congress blamed President Raúl Cubas Grau and the former army chief, Lino Oviedo Silva, for planning the assassination. Cubas resigned, and both he and Oviedo fled the country. Senate President Luis González Macchi then succeeded to the presidency of Paraguay. Richard W. Wilkie

Paraguay River, *PAIR uh GWAY* or *PAIR uh GWY,* is a waterway that flows south through Paraguay, cutting the country in two. It is a branch of the Paraná River and rises in south-central Brazil. From there, it flows south and joins the Paraná at the Argentine boundary. The Paraguay is 1,584 miles (2,549 kilometers) long. The Paraguay is a good river for navigation, except for channel shifts. Large steamboats go up the Paraná and continue on the Paraguay to Asunción, the capital of Paraguay. See also **Paraná River.** Richard W. Wilkie

green, red, blue, orange, yellow, or purple feathers. Their tails are either short and square, or long and pointed. The name also is spelled *parrakeet,* or *paroquet.*

Parakeets usually are affectionate and clever pets. They are natural acrobats, and can do many tricks on toy ladders and seesaws. The most common pet parakeet is the *budgerigar,* or *budgie.* This bird is native to Australia. It is also called the *budgerygah,* or *shell parakeet.* It lives well in captivity and becomes very tame.

You can tell the sex of an adult budgie by the color of the skin at the nostrils. This patch of skin is called the *cere.* In the male the cere is bluish, while in the female it is brownish. Most budgies can be trained to talk. It is best to start when the bird is only a few weeks old. Say the same word or phrase over and over until the budgie repeats it. Both the male and the female can learn many words. Some trainers believe males learn faster.

Many people enjoy the hobby of parakeet breeding. Amateur parakeet breeders often find the hobby both fun and profitable. The best time of the year for breeding is in the spring. Birds hatched in the spring will benefit from the sun and warmth of the summer. Special housing for the birds is necessary, because the space for one bird is inadequate for two. The female bird lays an average of five eggs. The eggs hatch in about 18 to 20 days. A parakeet may live 10 years or more.

Seeds and fruit are the chief parakeet foods. Wild parakeets nest in trees and are swift fliers. Many species live in warm parts of the world. The *ground parakeet* of Australia and Tasmania nests in bushes. The *lovebird* is a small, colorful African parakeet. One of the largest parakeets is the *slatyheaded parakeet* of India, Thailand, and Laos. The tiny *hanging parrot* of Southeast Asia is a parakeet that sleeps hanging upside down from a tree branch.

The *Carolina parakeet* once was common in the United States, ranging northward to New York and Illinois. The head of this parakeet was orange and yellow, and its body green. These parakeets have disappeared. Many of them were killed because milliners wanted their feathers for hat trimming. The last flock was seen in the Florida Everglades in 1904, but some of these parakeets may have survived until about 1920.

Scientific classification. Parakeets belong to the family Psittacidae. The Carolina parakeet is *Conuropis carolinensis.* Hanging parrots are genus *Loriculus.* Indian parakeets and lovebirds are *Agapornis.* Shell parakeets are *Melopsittacus,* and ground parakeets are *Pezoporus.* John W. Parallax, *PAIR uh laks,* is the difference in direction of an object when seen from two positions that are not in a direct line with each other and the object. Hold up one finger. Look at it first with one eye and then with the other. Notice how the finger seems to change position in relation to more distant objects when seen with one eye and then with the other.

When you look with two eyes, each eye sees nearby things from a slightly different direction. Your mind solves a parallax problem when you look at nearby objects, and you tell how far away they are. A person blind in one eye has no parallax vision, and may have difficulty judging the distance of nearby objects.

Parallax is used in surveying to tell how far away a distant object is. A base line of known length is laid off, the far-off object is viewed from each end of this base line, and the two angles with the base line are noted. Knowing the length of the base line and the number of degrees in the angles at each end, the height of the triangle can be solved by trigonometry.

Parallax is used in astronomy for finding the distance to the stars. For a base line, astronomers use the distance across the entire orbit of the earth around the sun, which is 186 million miles (299 million kilometers) long. But the stars are so far away that this base line is big enough to get the parallax only of some of the nearer

Paralysis, also called *motor paralysis,* is the loss of the ability to move *voluntarily* (under conscious control). It involves loss of control or function of the skeletal muscles, sometimes called *voluntary muscles* (see **Muscle** [Skeletal muscles]). Paralysis may be partial or complete, and temporary or permanent. It can affect any muscles and, in many cases, is associated with loss of sensation in the affected part of the body.

In order to move, a muscle must be stimulated by nerves. Paralysis can result from damage to (1) the central nervous system, (2) the peripheral nervous system, or (3) the muscles themselves.

Paralysis of central nervous system origin can be extensive. The central nervous system consists of the brain and the spinal cord. An injury or disease that destroys brain cells may paralyze arm, leg, and face muscles, often on only one side of the body. Such brain damage generally produces *spastic paralysis,* in which the muscles are more stiff than normal, and reflexes are overactive. If *motor nerve cells* (nerve cells that affect movement) in the spinal cord are damaged directly, then the muscles become limp, and reflexes are lost. This is called *flaccid paralysis.*

Disease of or injury to the spinal cord paralyzes the muscles at and below the level of damage. For example, spinal cord damage in the neck region can cause *quadriplegia*—paralysis of the arms and legs. *Paraplegia*—paralysis of the legs—follows damage to the spinal cord below the neck. Damage to the *brain stem*—the portion of the brain that connects to the spine—can result in the paralysis of muscles that control such automatic functions as breathing and swallowing.

Many conditions can produce paralysis of central nervous system origin. In newborns, such paralysis usually results from injury to the brain during the birth process or from brain hemorrhages in infants born prematurely. It can also result from spina bifida or other birth defects. Among children and young adults, automobile and sports accidents are leading causes of paralysis. Diseases that affect the central nervous system, such as meningitis and multiple sclerosis, also cause many cases of paralysis in young adults. Among older people, strokes and tumors are common central nervous system disorders resulting in paralysis.

Nerve cells in the central nervous system cannot regrow, and so their destruction generally results in permanent paralysis. However, some patients who have suffered brain damage can relearn certain movements by using undamaged parts of the brain.

Paralysis of peripheral nervous system origin generally affects an individual muscle or a group of muscles. The peripheral nervous system includes the nerves that connect the central nervous system to the muscles. Peripheral nerves can be damaged by various poisons, such as alcohol and lead; by diabetes and certain other diseases; and by cuts and other injuries. Inflammation of a peripheral nerve may also paralyze the muscles that the nerve controls. Peripheral nerves can regrow, and so this type of paralysis may be temporary in some cases. Physical therapy can help patients restore their strength if movement returns.

Paralysis of muscular origin. A group of hereditary disorders called *muscular dystrophy* ranks as the most common cause of paralysis due to muscle damage. For information on these disorders, see the article on **Muscular dystrophy.** Richard D. Penn

Paramaribo, *PAIR uh MAIR uh BOH* (pop. 180,000), is the capital, largest city, and chief port of Suriname, a country in northeastern South America. Nearly half of the people in Suriname live in Paramaribo. The city lies on the Suriname River, 12 miles (20 kilometers) inland from the Atlantic Ocean. For location, see **Suriname** (map). Industrial firms in Paramaribo manufacture aluminum, plywood, and various other products. The city is the home of the University of Suriname and the Suriname Museum. Paramaribo grew up around a British fort built in the mid-1600's. After the abolition of slavery in Suriname in 1863, many former slaves moved to Paramaribo. The city's population grew rapidly, and industrial development began in the mid-1900's.

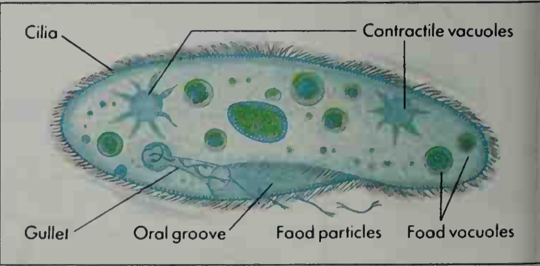
Paramecium, *PAIR uh MEE shee uhm,* is a tiny one-celled organism that can hardly be seen without the microscope. This type of organism is a *protozoan.* Paramecia live in ponds and slow-moving streams.



The paramecium is often compared to the *ameba,* another protozoan. Like the ameba, a paramecium is made up of watery material. The paramecium is clear on the surface and granular inside. On the inside, paramecia have one large nucleus and at least one smaller nucleus.

The paramecium has more special structures than the ameba. A stiff layer on the outside gives it a permanent shape, unlike the ameba. It looks like the bottom of a shoe. A paramecium is covered with fine hairs called *cilia.* It swims by beating its cilia. A network of fibers below the surface connects the cilia.

Food enters the paramecium through a hollow in one side called the *oral groove.* The oral groove leads to a tube called the *gullet.* Food in the gullet forms a ball which passes into the protoplasm as a food *vacuole.* The food is digested as the vacuole passes through the organism, and the waste is passed out from a special place called the *anal pore.*

Two star-shaped spots that seem to appear and disappear in the organism are the *contractile vacuoles.* They collect excess water and pass it to the outside.

Paramecia may reproduce by dividing in two across the middle. The nuclei divide, the rear half develops a new gullet, and the front half grows a new anal pore.

Then the paramecium breaks into two individuals. Paramecia also show the beginnings of sexual reproduction. Two individuals may come together and exchange their nuclei. This process is called *conjugation.* After conjugation, the paramecium separate and divide several times.

The paramecium shows an *avoidance behavior.* If it comes in contact with unpleasant stimuli, it reverses the movement of its cilia and backs up. Lawrence C. Wit

Scientific classification. Paramecia belong to the kingdom Protista.

Paramedic, *PAIR uh MEHD ihk,* is a trained medical worker who takes the place of a physician in certain situations. Most paramedics handle routine medical duties, giving doctors more time with patients who need their expert care. Some paramedics, called *Emergency Medical Technician-Paramedics* or EMT-paramedics, give on-the-scene aid if a doctor is not immediately available. These men and women have saved many people who might otherwise have died. This article discusses EMT-paramedics. For information about other paramedics, see **Medicine** (Other careers in medicine).

Duties. Paramedics give emergency care chiefly to accident victims and to people stricken by heart attacks or other sudden illnesses. Two or more paramedics usually work together as a team called a *Mobile Intensive Care Unit* (MICU). They use a special ambulance that carries a variety of drugs and medical equipment. This equipment includes a device called a *defibrillator,* which helps correct an irregular heartbeat.

Before treating a victim, paramedics use a two-way radio to contact a physician at a nearby hospital. They report the extent of any injuries, plus such information as the victim's pulse, blood pressure, and breathing condition. For victims of a heart attack, paramedics have an instrument that can send the doctor an *electrocardiogram,* a recording that describes heart activity. Such basic information helps the doctor determine the proper treatment. In serious cases, paramedics continue to treat the victim on the way to the hospital.

David R. Frazier

A team of paramedics provides emergency medical services. Such services include treatment for shock, bleeding, and heart attacks. Special equipment monitors the victim's bodily functions and sends a record of them to a nearby hospital.

Training. People who wish to become paramedics must complete an extensive medical training program given by a hospital or college. First they learn basic life-support techniques. These include treatment of shock and bleeding and restoration of breathing. Then the students learn such advanced medical procedures as treatment for heart attacks and the use of certain drugs. Graduates of the training program are certified by a hospital as Emergency Medical Technician-Paramedics. They must get additional instruction every year.

Paramedic service was introduced in the mid-1960's in the United States. Most major cities and their metropolitan areas have paramedic programs. Paramedics also serve many rural areas. David R. Boyd

Paraná, *PAIR uh NAH* (pop. 276,160), is a river port city in east-central Argentina. It is also the capital of Entre Ríos province. Paraná lies on the east bank of the Paraná River. A tunnel links it with the city of Santa Fe on the west bank. For location, see **Argentina** (political map).

Paraná is a shipping center for grain, cattle, and sheep raised in its region. It is also an administrative, cultural, and educational center and the site of a major air force base. Cement and glass are its only important manufactured products. Many of Paraná's buildings and parks overlook the river. The Plaza San Martín, in the city's center, has many fountains and a statue of José de San Martín, who led the fight for Argentina's independence from Spain. Paraná was founded in 1588, and a Spanish mission community was established there in 1730. From 1853 to 1862, it was the capital of Argentina.

Richard W. Wilkie

Paraná River, *PAIR uh NAH,* is the second longest river in South America, with a length of 2,485 miles (3,999 kilometers). Only the Amazon River is longer. The Paraná is formed in southern Brazil, where the Rio Grande and Paranaíba rivers meet. From there it flows south through Brazil and along the boundary between Brazil and Paraguay. Then it makes a boundary between Paraguay and Argentina and travels through Argentina. It empties into the Atlantic Ocean through the estuary known as the Plata River (Río de la Plata). Ocean vessels can travel through the estuary and up the Paraná as far as Rosario, Argentina, 400 miles (640 kilometers) from the Atlantic. The Paraguay River is the main branch of the Paraná River. Parasite, *PAIR uh syt,* is an organism that feeds and lives on another organism, called a *host.* Some author-

ities point out that all animals are parasites because they must rely on other living things for food. But in a stricter sense, parasites usually live on plants and animals bigger than they are. These organisms only feed on small amounts of the host's tissue or food at a time. They use the food to produce energy, and wastes are released directly into the host's body.

Parasites have varying effects on the body of their host. Experts believe that most parasites cause little or no harm to their host. For example, one type of ameba lives in human intestines. It feeds on partly digested food and other intestinal parasites without causing any obvious ill effects. Other types of parasites may cause great harm. For example, the *protozoans* (one-celled organisms) that cause malaria are parasites in the red blood cells of human beings.

Parasites that feed on people and animals cause many types of diseases. For example, one type of ameba destroys the lining of the intestines of human beings. This produces the painful disease called amebic dysentery. Other protozoans may invade the blood of mammals and cause diseases such as malaria and Texas cattle fever. Blood-sucking insects and ticks pick up parasites from infected animals and pass them on to other animals and human beings.

Parasitic flatworms and roundworms cause serious damage and often kill their hosts. One group of flatworms, called flukes, live in the intestines, liver, lungs, or blood of animals. Another group, the tapeworms, mature in the intestines of animals. They attach themselves to the intestinal wall with suckers or hooks. The tapeworms then absorb digested food, depriving the host of nourishment. Hookworms are the most harmful group of roundworms. They live in intestines and feed on the blood of their host.

Other parasites attack the skin. For example, parasitic fungi cause ringworm, a skin disease in human beings. Some insects, ticks, and mites feed by biting the skin of people and animals. Their bites are irritating, but the diseases these parasites spread are far more serious. Certain ticks transmit Rocky Mountain spotted fever to people. One type of mosquito spreads yellow fever and

another carries malaria. The tsetse fly transmits African sleeping sickness. People may get typhus from a body louse.

Insects, ticks, and mites may be parasitic only during particular periods of life. For example, only adult fleas are parasites. Red bugs and screwworms, a type of fly, are parasites only in their *larval* (infant) stage.

Parasites that feed on plants include various types of insects, roundworms, and fungi. *Aphids* (plant lice), scale insects, and threadworms may kill their plant hosts. Parasitic fungi cause wheat and bean rust, potato and tomato blight, apple scab, and downy mildew of grapes. Experts estimate that plant parasites destroy about $3 billion worth of crops in the United States each year.

Some species of plants live as parasites on other plants. For example, the dodder plant grows on and kills alfalfa, clover, and flax. Mistletoe, a parasite of forest trees, is called a *partial parasite* because it makes some of its own food.

Most *bacteria* (one-celled organisms) are parasites. Bacterial diseases, such as tuberculosis and pneumonia, are usually considered apart from those caused by other parasites. Jacqueline R. Shepperson

Parathyroid gland, *PAR uh THY royd,* consists of four tiny glands that function as one gland. These glands lie in the front of the neck close to the thyroid gland. The parathyroid glands secrete parathyroid hormone (PTH), also called *parathormone,* into the blood. PTH helps regulate the amount of calcium and phosphate in the body. These minerals are necessary for a number of important body processes, including bone growth and muscle and nerve function.

When the level of calcium in the blood becomes low, the parathyroid glands increase secretion of PTH. PTH causes the kidneys to produce urine that contains less calcium and more phosphate than normal. The urine is then expelled from the body. PTH also frees calcium and phosphate from bone. In addition, PTH increases the amount of calcium absorbed from the digestive tract.

Malfunctioning of the parathyroid glands can lead to low levels of calcium in the blood. Severe calcium deficiency results in *tetany,* a dangerous condition involving chronic muscle spasms. Charlotte H. Greene

Parcel post is a postal service for carrying packages. The governments of the United States, Canada, and most other countries carry parcels as part of their regular postal services.

The United States established its parcel post service in 1913. The U.S. Postal Service divides all mail into five classes. Parcel post consists of fourth-class mail that weighs from 1 to 70 pounds (0.45 to 32 kilograms). Items mailed through parcel post also must not exceed a certain size. The size is determined by adding the length of the parcel's longest side and the distance around the parcel at its thickest part. The sum of these measurements must not exceed 108 inches (274 centimeters). Parcel post charges are based on the parcel's weight and on the distance the parcel must travel.

In the United States, almost any kind of merchandise may be mailed through parcel post, including day-old live poultry, baby alligators, and bees. However, parcel post cannot be used to send explosives, materials easily set on fire, or other merchandise that might be dangerous to handle.

Parchment is an animal skin that has been prepared as a surface for writing. The word *parchment* usually means a writing material made from the skins of sheep, goats, or calves. Such materials are very durable. Parchment scrolls have survived from about 1500 B.C.

In making parchment, the skins are first washed and then placed in lime to remove the hair and fat. Next, the skins are stretched on a frame and thinned with knives and scrapers. Finally, the skins are rubbed with chalk and pumice in order to create a smooth, white writing surface.

A form of fine, high-quality parchment called *vellum* is made from the skins of calves, kids, or lambs. Vellum has been used for important writings such as charters, university diplomas, and wills. *Heavy parchment* is made from the skins of calves, donkeys, goats, and wolves. It is used for drumheads. *Parchment paper,* also called *vegetable parchment,* is made by dipping pure, unsized paper into a cooled mixture of sulfuric acid and water, and then washing and drying it under pressure. This process makes the paper partly transparent and much stronger than ordinary paper. Parchment paper is used for legal documents and maps.

Parchment was especially popular in the ancient cities of Asia Minor. The Jews, Persians, and other ancient peoples used it for sacred and literary writings. Beginning about 200 B.C., parchment gradually replaced papyrus as the most commonly used writing material. Parchment remained the leading writing material in the West even after the introduction of paper from the Middle East in the A.D. 1000's. Paper largely replaced parchment about the time printing was being developed in Europe during the 1400's. Parchment is still sometimes used for important documents. Paul H. Mosher

Pardon is the act of releasing a person from the legal penalties for a crime the person has committed. Offenders can be pardoned before or after they are convicted. Pardons are granted by chief executives, such as kings, presidents, and governors. The executive sometimes acts on recommendations made by others.

Pardons differ from paroles. Parole is a continuation of a sentence away from prison, and paroled prisoners must follow certain rules. But a person who receives a pardon is entirely free. The person is not regarded as

a criminal, because the pardon has the effect of wiping out the conviction. The pardon may also be used to free a person whose innocence is established after conviction. State governors grant many pardons to restore civil rights to offenders who have served their sentence and have been properly rehabilitated. James O. Finckenauer

Paré, *pa RAY,* **Ambroise,** *ahm BRWAZ* (1510?-1590), a French surgeon, made important contributions to the use of surgery in medicine. Paré stopped treating gunshot and surgical wounds by pouring boiling oil over them, which was the practice at that time. Instead, he came to rely on the power of nature to heal his patients. His motto was, "I bandaged him, God healed him." In Paré's day, doctors considered surgery beneath their dignity, and most operations were performed by barber-surgeons. Paré's work helped to raise the standing of surgery.

Paré was born at Bourg-Hersent, near Laval. His formal education was sketchy, but he served as an apprentice to a barber-surgeon and learned on the battlefield as a surgeon in the French army. In 1552, Paré became surgeon to Henry II of France. He later became first surgeon to Charles IX and Henry III. Paré died on Dec. 22, 1590. Matthew Ramsey

Parent is a father or mother. There are two types of parents, *biological parents* and *social parents.* A child's biological parents are the man and woman who physically produce the baby. They contribute the mental and physical characteristics that the child inherits. The child's social parents—who may not be the same as its biological parents—are the ones who raise the child. This article discusses social parents.

The role of parents is to provide care, love, and training for their children. Children must have years of physical care, including food, shelter, and protection from harm. Love and affection are also necessary to stimulate children to learn and grow. This love should come from a person or from people with whom the children can develop a lasting attachment. Youngsters raised in institutions who did not get enough individual attention or love often experience problems forming personal relationships later in life. They may also fail to achieve other kinds of normal growth and development, though they receive the necessary physical care.

Parents play a major role in a process called *socialization,* by which children learn to become independent members of society. For example, parents train their youngsters to speak, to dress themselves, and to perform other basic activities. Girls and boys also learn *sex roles*—that is, the roles they are expected to play as adult females or males—by identifying with the parent of the same sex.

Children are born with great individual differences in intelligence, physical ability, and temperament, and so they vary greatly in talent, personality, and other characteristics. Although parents greatly influence a child's development, they are not completely responsible for his or her strengths and weaknesses. Other influences, over which parents have little control, also affect a child's attitudes and development. These influences may include friends, teachers, and even characters on television.

Changes in parenthood have resulted from the many scientific, economic, and social changes during the last hundred years. Early American parents expected their children to contribute to family support and to perform many adult tasks by the age of 6 or 7. During the 1800's, most children became independent and self-supporting as teen-agers. Today, childhood is more prolonged and parents spend more years and more money raising their children.

People today have greater freedom than ever before in deciding whether to become parents. Modern birth control methods allow couples to choose how many children, if any, they wish to have and when to have them. Also, scientists have developed techniques that permit women beyond the traditional childbearing age to bear children.

Another change is that greater numbers of women have entered the work force. Today, most American mothers with school-age youngsters work outside the home. The traditional division of tasks between parents has changed. Many fathers are now more active in the care of children and the home.

Children today are dependent upon their parents' care for a longer time, but many mothers are seeking to expand their role beyond that of a parent. As a result, there is a shortage of child care. Day-care programs provide one solution (see Day care).

In the past, young parents got help and instruction in child rearing from their own parents or other relatives. Today, less than 5 percent of the families in the United States have an extra adult who shares parental responsibility. This lack of help, plus the increased duration of obligations to children, has created a need for information about raising children. The need accounts for the popularity of child-care books and *parent education* groups or courses. Robert H. Abramovitz

Parent education helps parents or future parents to acquire the practical and emotional skills needed to raise children. Mothers and fathers develop some of these skills informally, by recalling how they themselves were brought up and by trial and error. They also learn by watching other parents and by sharing experiences and ideas with them. However, almost all parents find that raising children is more challenging than they expected it to be. As a result, many parents supplement informal learning with formal activities specifically designed to teach skills of parenthood. This article discusses the type of formal parent education that is offered by schools, social service agencies, churches, and other organizations.

Changing family life contributed to rapid growth of parent education programs during the late 1900's. The

traditional American family once consisted of a working father, a mother who did not work outside the home, and their children. New parents were likely to live near their own parents, who helped with child care and provided advice and support. Today, many young mothers and fathers live far away from their own parents. Both parents in two-parent families often work outside the home, and many other families are headed by a single working parent. In addition, growing numbers of unmarried pregnant teen-agers keep and raise their babies.

These new patterns may increase stress and loneliness for parents and dull their pleasure in raising children. In severe cases, pressure and isolation can lead parents to abuse drugs or alcohol or to neglect or abuse their children. Parent education programs help mothers and fathers cope with a wide range of challenges, from minor frustrations to major hardships.

Methods of parent education

Parent education may be organized in different ways. Some groups consist of parents who have children of similar ages. Another type is made up of parents who share a common experience, such as having been abused themselves as children. A third type brings together parents who want to learn a skill, such as giving children a voice in family decisions. Methods of parent education include (1) media-based education, (2) study groups, (3) observation and participation, (4) home visitation, and (5) group training.

Media-based education reaches people through books, magazines, newspapers, television, radio, computers, and other sources. Many how-to books provide parenting advice. Magazines, newspapers, TV, and radio cover many topics of interest to fathers and mothers. Computers also offer a wide variety of resources, including access to the worldwide information network called the Internet.

Study groups meet to explore approaches to raising children. Some groups focus on one particular method. Others investigate a wide range of topics and theories. Study groups enable parents to talk with others who have similar situations and to learn from one another. Many such groups teach parents strategies for understanding relationships within families. Parents also learn to express themselves effectively and to listen carefully to each other and to their children.

Observation and participation take place in a classroom or other instructional setting. An expert demonstrates various techniques for mothers or fathers. The parents then practice their newly learned skills with their children while the expert supervises their efforts.

Home visitation helps parents encourage their children's development. Experts known as *home visitors* call on parents and show them how to use books, toys, and everyday activities to teach ideas and skills. The visitors may also leave educational materials for the family to use until the next visit. Home visitation tailors parent instruction to the particular needs of each father, mother, and child.

Group training, like home visitation, focuses on preparing parents to teach their children. The parents work in groups, however, rather than individually with a home visitor.

Family support programs

Family support programs, also called *family resource programs,* provide child-rearing education and extensive assistance to families of young children. These community-based programs are designed to provide the greatest possible opportunity for each child's growth and development. Family support programs may offer counseling and telephone call-in services that provide information, advice, or crisis assistance. The programs also encourage exchange of information among parents to build informal support networks. Family support programs put parents in contact with agencies and organizations that can assist them in raising their children. The programs match the type and amount of support to each family's needs. Many states have passed laws to establish these programs in schools, hospitals, and community service agencies.

History

The parent education movement in the United States began during the late 1800's and early 1900's. Many organizations concerned with parenthood were established during this period, including the National Congress of Mothers, which is now the National Congress of Parents and Teachers (National PTA).

The government also became active in helping parents during this period. In 1912, for example, a federal agency called the Children's Bureau was established. It distributed information on child development and published popular pamphlets, including *Infant Care* and *Your Child from One to Six.* The Smith-Lever Act of 1914 set up what is now the Cooperative Extension System, which provides advice about child care.

The 1920's marked the beginning of scientific study of child development. Many universities established child study centers, where researchers investigated the growth and development of children and applied their findings to educational methods.

Parent education has expanded greatly since 1960, partly because of increased government support. In 1965, for example, a federal project called Head Start was set up to help low-income parents prepare their children for school (see **Head Start**). Education for Parenthood, another federal government project, helps schools develop courses for teen-agers.

Parent-teacher organizations are volunteer groups that work in communities to improve the education, health, and safety of children and youth. To achieve these goals, these organizations encourage close cooperation between home and school. Parent-Teacher Associations, abbreviated PTA's, are among the best known and most active of these groups in the United States. Other parent-teacher organizations include Home and School Associations, various local parent advisory committees, and school-based councils.

Parent-Teacher Associations

PTA's are associated with the National Congress of Parents and Teachers. These local associations also work with their state branch of the national organization. Most local PTA's function in public and private schools at the elementary, junior high, and high school levels.

Each local PTA draws up its own constitution, using the rules of the National Congress as guidelines. The constitution outlines the local unit's specific purposes, procedures for holding meetings and planning programs, and rules for electing officers.

Membership in a PTA is open to anyone who wishes to help the organization achieve its objectives. A person who joins a local PTA automatically becomes a member of the state and national organizations as well.

Purpose. Each local PTA unit develops programs to suit the needs of its school and community and to fit the basic goals of the National Congress of Parents and Teachers. These goals, called *Objects,* of the National Congress urge cooperation between parents and educators to give students all possible advantages in mental and physical education. The Objects also call for improvement of the environment of children and youth in their home, school, and community. See **National Congress of Parents and Teachers**.

Activities and programs. Most PTA's hold meetings regularly during the school year. These sessions bring parents and other citizens into schools to learn about courses of study and teaching methods.

Most meetings include open discussions of the needs and problems of the school and the community. These discussions may lead to such organized efforts as campaigns to obtain new classroom equipment, build additional playgrounds, or improve traffic safety. In some cases, the National Congress gives information and materials to local PTA associations to carry out projects.

Local PTA's organize field trips, set up tutoring programs in arithmetic and reading, and conduct health examinations. They also develop study-discussion groups in family life and other areas of parent education. Many local PTA units sponsor programs dealing with such matters as career and employment opportunities, delinquency, drug abuse, and intercultural understanding.

PTA's often work with other community service organizations, including the American Legion, Boy and Girl Scouts, and the Neighborhood Youth Corps. Many PTA's, together with such community groups, have worked for Head Start, a program of education and health for economically deprived preschool children. PTA members also have helped provide books for small, poorly equipped schools in Appalachia, an economically depressed region in the eastern United States.

Parent-Teacher-Student Associations (PTSA's), like PTA's, are associated with the National Congress of Parents and Teachers. Most PTSA's began as local PTA units in high schools. They expanded to include students, so that the young people could take an active role.

PTSA's give students a role in planning the educational programs of public and private high schools. Some PTSA's have helped develop new methods of instruction that provide greater opportunities for self-directed learning and independent study. Other PTSA's have encouraged student governments to become more active. PTSA's also work to include parents and children from all cultural, ethnic, and economic groups in school activities.

Other parent-teacher organizations

Home and School Associations are parent-teacher organizations that function chiefly in Roman Catholic schools. They promote a close working relationship between parents and teachers to further the goals of Catholic education. Home and School Associations also encourage parents to take an active interest in neighborhood conditions that influence children's behavior. The associations try to improve their communities to help solve behavior problems among young people. Many local Home and School Associations cooperate with other community groups in promoting the care and protection of children and youth.

Home and School Associations develop their programs through committees and projects at the national, regional, and community levels. Most local associations operate in individual *parishes* (church districts). Several parishes also may combine to form an association.

Various public schools and non-Catholic private schools also have parent-teacher groups called Home and School Associations. The goals and services of these groups resemble those of the associations that function in Roman Catholic schools.

Local parent advisory committees have been formed in a number of public and private schools throughout the United States. Many of them assist in government-sponsored education programs for the children of underprivileged families. The federal Elementary and Secondary Education Act of 1965 requires officials of local schools to permit parents to take a direct part in planning and operating such programs. Parent advisory committees also help school administrators carry out programs that meet the educational needs of children at various schools.

School-based councils have been established through legislation in several states. These councils are formed by individual schools and include parents, teachers, and other community members. A school-based council helps a principal make improvements in a school. Stephen M. Fain

Parents Without Partners is an organization of men and women who are raising children in a home that has only one parent. These parents may be divorced, separated, or widowed, or they may never have been married. The organization works to help its members and their children build satisfying lives in a society in which most homes have two parents.

Local chapters of Parents Without Partners are in the United States, Canada, and four other countries. The chapters sponsor discussions and speakers, as well as family recreational activities. Teen-agers may have their own chapters.

Parents Without Partners publishes a magazine, *The Single Parent,* and maintains a library of publications and tapes dealing with the problems of single parenthood. The organization works for better laws for single-parent families. It sponsors conventions, seminars, and other meetings. Parents Without Partners was founded in 1957 and has headquarters in Boca Raton, Florida.

Pareto, *pah REH toh,* **Vilfredo,** *veel FRAY doh* (1848-1923), was an Italian sociologist and economist known chiefly for his theories on political behavior. He believed that people base political decisions and all other actions on emotion, instinct, and similar drives—rather than reason. He also maintained that all societies are governed by a small group of rulers called an *elite.* According to Pareto, the elite is continually overthrown and replaced by people from the lower ranks, who become the new elite. He called this process the *circulation of elites.*

In economics, Pareto theorized that the amount of consumer satisfaction with a product cannot be measured. However, consumers can rank products in order of preference, unless they are indifferent about which of two or more products they buy. This idea led to the development of *indifference analysis,* a method of studying consumer behavior. Pareto also developed new ways to apply mathematics to economic problems.

Pareto was born on July 15, 1848, in Paris. He worked as a civil engineer before taking up sociology and economics. Pareto's books include *A Manual of Political Economy* (1906) and *The Mind and Society* (1916). He died on Aug. 19, 1923. Irving M. Zeitlin

Paretsky, Sara (1947-), an American author of detective stories, is the creator of the female private investigator V. I. Warshawski. The success of the Warshawski series is credited with helping to break down barriers to realistic portrayals of female detectives in fiction.

Paretsky was born on June 8, 1947, in Ames, Iowa. She worked for a research company in Chicago from 1971 to 1974. After three years as a free-lance writer, she worked for a Chicago insurance company from 1977 to 1986, when she decided to become a full-time writer. Paretsky received M.B.A. and Ph.D. degrees from the University of Chicago in 1977.

Paretsky introduced the Warshawski character in *Indemnity Only* (1982). Warshawski is tough, independent, and resourceful. She has strong sympathies for people victimized by the rich and powerful. Paretsky sets her Warshawski novels in Chicago. Most of her stories involve the city's working-class neighborhoods as well as corporate and political corruption.

In 1986, Paretsky helped found Sisters in Crime. The organization promotes women writers of detective fiction and tries to improve the image of women in detective stories. Paretsky also writes short stories and articles and has edited a number of anthologies of detective stories written by women. Jon L. Breen

Paricutín, *puh REE kuh TEEN,* is the most recent volcano to form in the Western Hemisphere. It stands near the city of Uruapan in southwestern Mexico (see **Mexico** (terrain map)). It was named for the village of Paricutín, which was destroyed by the volcano.

The volcano appeared in a cornfield on Feb. 20, 1943, from a crack in the earth. Volcanic material began to erupt from the crack and formed a cone around the opening in the earth. By the end of one week, the cone stood about 450 feet (140 meters) high. In two months, it reached about 1,000 feet (300 meters).

Paricutín's lava destroyed the villages of Paricutín and San Juan Parangaricútiru and damaged nine other villages. It also turned an area of farmland and forests into wasteland before it appeared to cease activity in 1952.

Today, Paricutín stands 1,345 feet (410 meters) above its base and 9,213 feet (2,808 meters) above sea level. Lava from Paricutín covers about 9 square miles (24 square kilometers), and volcanic ash and sand extend over 19 square miles (50 square kilometers). Paricutín, like many other volcanoes in southern Mexico, is part of the *Volcanic Axis,* also called the *Transversal.* The Volcanic Axis is a line of volcanoes that extends across Mexico in an east-west direction. Paris, in Greek mythology, was a son of Priam, king of Troy. Paris's mother, Hecuba, dreamed that her unborn son was a torch that set the country on fire. A soothsayer said the dream meant the child would cause the destruction of Troy. Priam gave Paris to a slave and ordered him to kill the child. The slave left him to die, but a shepherd saved him and raised him as his own son. Paris married the nymph Oenone.

One day, messengers came from Priam to take a bull as a prize for a wrestling contest. They took Paris's favorite bull, so he entered the contest and won it back. His sister Cassandra recognized him, and Priam accepted him, disregarding Hecuba's dream.

Zeus, the king of the gods, had Paris judge a contest among three goddesses—Aphrodite, Athena, and Hera—over the Apple of Discord. This apple bore the words "To the fairest." Aphrodite promised Paris the most beautiful woman in the world, and so he chose her over the other goddesses. Hera and Athena hated him and Troy after that.

Paris fell in love with Helen, the beautiful wife of Menelaus, and took her to Troy. Menelaus was the king of Sparta, in Greece. Agamemnon, Menelaus's brother, led the Greeks in the Trojan War to get Helen back. Late in the war, Paris killed the Greek hero Achilles with a bow and arrow, but was himself later killed by the Greek archer Philoctetes. Cynthia W. Shelmerdine

The heart of Paris includes many beautiful buildings that are hundreds of years old. The Seine River flows around the île de la Cité (Island of the City), *right.* The magnificent Cathedral of Notre Dame towers above the other buildings on the island.

Paris

Paris is the capital and largest city of France. It is one of the most beautiful cities in the world. Lovely gardens and parks and historic squares lie throughout Paris, and chestnut trees line the city's famous avenues. At night, floodlights shine on Paris's many magnificent palaces and monuments. The gleaming beauty of Paris has given it the nickname *City of Light.*

Every year, more than 2 million tourists visit Paris. The most popular attraction is the Eiffel Tower. This huge structure is known throughout the world as the symbol of Paris. Tourists flock to the Louvre, one of the world's largest art museums, and visit the soaring Cathedral of Notre Dame. Paris is also famous for its many restaurants, sidewalk cafes, theaters, and nightclubs.

Paris has long been a world center of the arts and education. For hundreds of years, important styles in painting and literature have developed there. About two-thirds of France's artists and writers live in Paris. The University of Paris, one of the largest universities in the world, is more than 800 years old.

The Paris area is also a great industrial center. About a fourth of France's labor force lives in the crowded area. Factories in and near Paris turn out a wide variety of products, including most of France's automobiles. Paris is known for such luxury products as expensive jewelry, perfume, and women's high-fashion clothing. Famous designers of women's clothing create Paris fashions that are copied in many other countries.

The history of Paris goes back more than 2,000 years. In 52 B.C., soldiers of ancient Rome found in the area a

tribe of people who lived by fishing. The Romans established a colony there. During the Middle Ages, Paris grew rapidly and became a major center of culture and government. In Paris, in 1792—during the French Revolution—France became one of the first nations to overthrow its king and set up a republic. In World War I (1914-1918), Paris cabdrivers helped win the First Battle of the Marne by speeding French troops to the front in their taxicabs. German forces occupied Paris during World War II (1939-1945).

More than 2,000 years ago, the Roman general Julius Caesar described the people of what is now Paris as "clever, inventive, and given to quarreling among themselves." This description is still considered true today. Parisians are known for their creative arts and crafts, and their strong political feelings lead to many bitter quarrels. The similarities among Parisians through thousands of years help prove a French saying: "The more things change, the more they stay the same."

Today, dramatic changes are taking place in Paris. Modern office and housing complexes are being constructed in the city, along with new cultural and recreational structures. At the same time, its beautiful old buildings and monuments are being restored. Paris is staying young while preserving the treasures of its past.

The city

Paris lies 107 miles (172 kilometers) southeast of the English Channel. It is in the heart of a fertile, heavily populated lowland called the Paris Basin. Paris has a population of about 2,150,000 and is one of the world's most crowded cities. It has an average of 52,000 people per

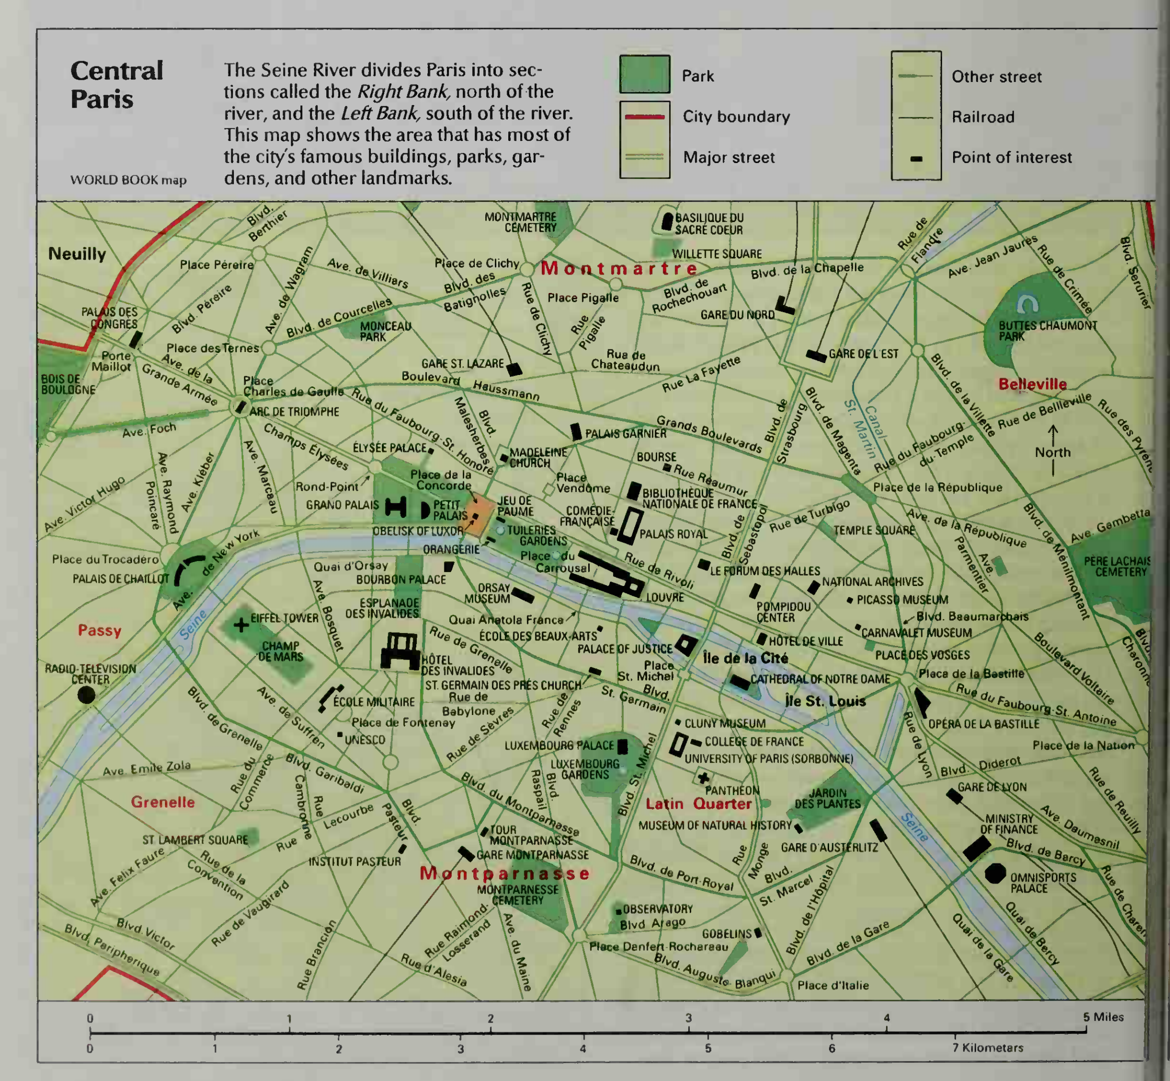
square mile (20,500 per square kilometer).



The Seine River curves through Paris for about 8 miles (13 kilometers) from east to west. The section of Paris north of the river is called the Right Bank. Busy offices, small factories, and fashionable shops are on the Right Bank. The Left Bank, south of the Seine, is a famous center of artist and student life.

Paris is laid out according to plans that developed through hundreds of years. An island in the Seine, the île de la Cité (Island of the City), is the heart of Paris. The city was founded on this island more than 2,000 years ago. Paris soon spread out on both banks of the river. About 1200, a fortified wall was built around the city. Paris continued to grow, and new walls were built in a series of widening circles. Today, there are boulevards where the walls once stood.

Gardens, squares, and parks. Paris has been described as being like a woman with flowers in her hair. This description comes from the many beautiful gardens and parks throughout the city. The Tuileries Gardens, on the Right Bank, are one of the finest formal French gardens. Neat flower beds and beautiful statues line a long path through the Tuileries. Children sail toy boats in two round fountains along the broad path. They also sail boats in the central pool of the Luxembourg Gardens, on the Left Bank. See **Tuileries.**

The Champs Élysées (Elysian Fields) is Paris's most famous avenue. It is lined with beautiful gardens and rows of chestnut trees. Along its route is the Rond-Point. This landscaped circle has magnificent fountains, and formal flower beds trimmed to look like a huge bouquet. At the western end of the Champs Élysées stands the Arc de Triomphe (Arch of Triumph). Emperor Napoleon I started to build this huge stone arch as a monument to his troops in 1806. It was completed in 1836. The arch rises in the Place Charles de Gaulle (formerly the Place de l'étoile), one of more than 130 public squares in Paris. Broad avenues extend from the square in 12 directions. See **Arc de Triomphe.**

At the eastern end of the Champs Élysées is the Place de la Concorde (Square of Peace). This square was built during the 1700's. Within it are eight huge statues, two fountains, and the Obelisk of Luxor, a stone pillar from Egypt. The Obelisk of Luxor stands 75 feet (23 meters)

high. During the French Revolution (1789-1799), a *guillotine* (beheading machine) stood in the Place de la Concorde. Hundreds of people, including King Louis XVI and Marie Antoinette, were executed on this guillotine. Other important squares in Paris include Carrousel, Nation, République, St. Michel, Vendôme, and Vosges.

The Champ de Mars (Field of Mars) is a beautiful park that was once a military training ground. Among its gardens and treelined lawns are many attractions for children, including miniature automobile speedways, merry-go-rounds, and donkey rides. In the Champ de Mars stands the Eiffel Tower. This world-famous symbol of Paris rises 984 feet (300 meters). Visitors can dine in restaurants on various platforms in the tower and enjoy spectacular views of Paris. See **Eiffel Tower**.

Paris' largest parks are the Bois de Boulogne (Forest of Boulogne) and the Bois de Vincennes (Forest of Vincennes). These parks have several lakes for boating, horse-racing tracks, restaurants, theaters, and zoos.

Famous buildings. The Louvre Palace, one of the largest palaces in the world, extends $\frac{1}{2}$ mile (0.8 kilometer) along the Seine. The palace houses the Louvre Museum, one of the world's largest art museums. The Louvre dates from about 1200, when it was built as a royal fort. It was rebuilt during the 1500's as the royal palace. From then on, many French rulers expanded the Louvre. Napoleon III began to build the last addition in 1852. From 1984 to 1989, the Louvre's exhibition space was restored and enlarged, and a modern glass pyramid entrance was built in the courtyard. The modern entrance contrasts sharply with the traditional architecture of the Louvre building itself. See **Louvre**.

A number of historic buildings of Paris house government offices. The main house of France's Parliament, the National Assembly, meets in the Bourbon Palace, completed in 1728. The Luxembourg Palace is the meeting place of the Senate, the less powerful house of France's Parliament. The palace was built during the early 1600's.

Today, high French courts meet there. The Hôtel de Ville (City Hall) stands where Paris' first town hall was built in 1357.

The domed Panthéon is a monument to French heroes and other famous people. It was originally a church named for Sainte Geneviève, the patron saint of Paris. In A.D. 451, she organized the city's defenses against a threatened attack by Attila the Hun. It is believed that her prayers prevented the attack and saved the city. In 1791, the church was named the Panthéon, and became a burial place. Jean Moulin, a hero of World War II, was buried there in 1965. After German troops occupied France in 1940, Moulin organized forces to fight them. The Germans captured Moulin and tortured him to make him name his friends. Moulin tried to kill himself so he would not weaken and betray them. He later died from the torture.

The Cathedral of Notre Dame, the most famous of Paris' many beautiful churches, stands on the Île de la Cité. The cathedral was completed in the mid-1200's, and is known for its majesty and stone carvings (see **Notre Dame, Cathedral of**). Many Roman Catholic pilgrims visit the Basilique du Sacré Coeur (Basilica of the Sacred Heart). This basilica, with its huge bell tower and onion-shaped dome, is one of the city's most familiar sights. The gleaming white church rises atop Montmartre, Paris' tallest hill at 423 feet (129 meters) high.

Arts. Paris has long been famous as a world center of the arts. Thousands of actors, musicians, painters, and writers work or study there. Many of them live in the Montmartre district. They come from all parts of France and from many other countries. They are attracted by Paris' special atmosphere of freedom in the arts, in which new styles can develop. Painters and sculptors show their work at exhibitions called *salons,* and in the city's many art galleries. Outstanding painters and sculptors who lived in Paris include Georges Braque, Pablo Picasso, Pierre Auguste Renoir, and Auguste Rodin. Famous novelists and playwrights who lived in Paris include Albert Camus, André Gide, Victor Hugo, Marcel Proust, and Jean-Paul Sartre.

Paris has about 60 theaters. The Comédie-Française, Paris' most famous theater, offers classics of French drama. The Opéra de la Bastille presents opera. The Palais Garnier, which formerly housed the opera and was generally called the Opéra, holds dance programs. Paris also has several symphony orchestras.

Museums and art galleries of Paris are storehouses of many priceless art treasures. The works of painters and sculptors of the late 1800's and the 1900's are displayed in the National Museum of Modern Art in the Georges Pompidou National Center of Art and Culture. The Pompidou Center also houses a public library and music and industrial design centers. The famous Louvre museum displays works considered to be of lasting greatness. It houses such masterpieces as Leonardo da Vinci's *Mona Lisa* and the Greek statue *Venus de Milo.* The huge Louvre building also houses the Museum of Decorative Art. This smaller museum has a fine collection of antique French furniture. The Picasso Museum, originally a mansion built in the 1600's, exhibits many of

The museum is a converted railroad station built in 1900. The Orangerie and the Jeu de Paume museums stand across from one another on the Place de la Concorde at the end of the Tuileries Gardens. The Orangerie's collection includes European paintings of the late 1800's and early 1900's. The Jeu de Paume displays contemporary art.

The Army Museum is one of the world's largest military museums. It has outstanding collections of historical weapons and armor. Nearby is the tomb of Napoleon I. The museum and tomb stand on the grounds of the Hôtel des Invalides (Home for Disabled Soldiers), completed in 1676. The Cluny Museum, a house built in the 1400's, has artworks and other objects of the Middle Ages. The Carnavalet Museum, a house dating from the 1500's, has displays that tell the history of Paris.

Schools and libraries. The University of Paris dates from the 1100's. It developed in an area on the Left Bank that has been called the Latin Quarter since the Middle Ages. At that time, the students and teachers who lived there spoke to one another in Latin. Today, the university has 13 units in the city and its suburbs (see **Paris, University of**). The world-famous École des Beaux-Arts (School of Fine Arts) offers courses in drawing, engraving, painting, and similar subjects (see **École des Beaux-Arts**). Other educational institutions in Paris include the College of France and the Polytechnical School.

The Bibliothèque Nationale de France, France's national library, is one of the largest libraries in Europe (see **Bibliothèque Nationale de France**). Other important Paris libraries include the Mazarine Library of the Institute of France, the nation's major learned society, and libraries of the University of Paris.

Economy. Paris is the chief financial, marketing, and distribution center of France. Many company headquarters and banks and other financial institutions operate in the city. Over half the nation's business is done in Paris. Jobs provided by the national and local governments contribute greatly to the city's economy. Paris and its surrounding area make up the country's major manufacturing center. The Paris region is the center of the great French automobile industry. Other important Paris industries include book publishing and the manufacture of chemicals, dyes, electronic machinery, furniture, leather goods, and railroad and airplane equipment. Paris has long been a world center of such luxury goods as expensive jewelry, perfume, and women's high-fashion clothing. These famous *articles de Paris* are produced in many small plants in the heart of the city. They are sold in fashionable shops on the Right Bank.

Paris is the transportation center of France. The national railroad network forms a cobweb pattern, with most lines extending from Paris in all directions. Three major airports serve Paris—Charles de Gaulle, Le Bourget, and Orly. The Paris subway, called the Métro, has more than 100 miles (160 kilometers) of track. The Regional Express Network is a suburban commuter train system that links Paris with its suburbs. The trains travel at about 60 miles (96 kilometers) per hour.

Paris has about 10 daily newspapers. They account for about a third of the circulation of all French dailies. The largest Paris paper, *France-Soir,* has a daily circulation

of more than 800,000 copies. *Le Monde,* another Paris paper, is world famous. Six major television networks and nine radio networks also operate from Paris. Almost half of them are government-owned.

Government. A mayor serves as the head of government. A city council makes the city's laws. The 109 council members are elected by the people to six-year terms. The council members elect the mayor to a six-year term. Paris is divided into 20 local government units called *arrondissements* (wards or districts). A commission handles the government affairs of each *arrondissement.*

From the 1870's until 1977, prefects appointed by the national government headed the government of Paris. In 1977, a mayor became the head of government.

History

Early years. In ancient times, a Celtic tribe called the Parisii lived in what is now Paris. The Parisii occupied an island in the Seine River. The island is now called the île de la Cité. In 52 B.C., Roman invaders established a colony there and called it Lutetia. The town soon spread out on both banks of the river. It became known as Paris about A.D. 300.

Clovis, the first ruler of the great Frankish kingdom, made Paris his capital in 507. Hugh Capet, the count of Paris and duke of the surrounding region, became king of France in 987. As the French kings gained power, the capital grew in importance and population. Philip II, who ruled from 1180 to 1223, developed Paris as a center of culture, government, and learning.

The Renaissance. The French kings further developed the culture and beauty of Paris during the Renaissance, a revival of art and learning that lasted from the 1300's to the 1500's. The people they hired to design the new boulevards, palaces, and squares looked to ancient Greece and Rome for models. The Louvre, a fortress dating from about 1200, was rebuilt as the royal palace during the 1500's. Many French rulers later built additions to the Louvre and made it the largest palace in the world. Paris was the center of the bloody French Revolution (1789-1799). See **French Revolution.**

The Napoleonic era. During the early 1800's, Napoleon Bonaparte built many new buildings, laid out public gardens, and made other improvements in Paris. Napoleon III, emperor from 1852 to 1870, did much to give Paris its present appearance. He built banks, hospitals, railroad stations, theaters, and wide avenues.

Paris in wartime. In the Franco-Prussian War (1870-1871), Paris surrendered to Prussian troops after a hard siege in which the city's food supplies were cut off. The starving Parisians ate cats, dogs, and rats to stay alive. See **Franco-Prussian War.**

The Germans did some damage to Paris with long-range guns in World War I (1914-1918) but did not capture the city. In September 1914, the Germans pushed French troops back to the Marne River, about 15 miles (24 kilometers) from Paris. The French held their ground, and taxicabs from Paris brought out fresh troops. This "taxicab army" helped win the First Battle of the Marne, which ended Germany's chances for a quick victory.

German troops occupied Paris during World War II (1939-1945). They broke through the French defenses in June 1940 and pushed quickly to Paris. To save Paris from destruction, the French government declared it an *open city,* an undefended city opened to the enemy. German troops entered Paris without a fight and marched triumphantly down the Champs Élysées. Paris became a center of French underground resistance. In mid-1944, Allied troops began driving the Germans from France. The Allies freed Paris in August 1944.

Renewal and new construction. In 1960, a vast renewal program was drawn up, scheduled for completion in 2000. Old buildings and other facilities that would not be able to serve the future population were scheduled to be replaced. Old monuments, palaces, and other buildings valuable for their beauty began to be restored. A 1961 amendment required all building owners to sandblast and wash the front of their property. By the mid-1960's, Paris was a gleaming city. Since then, many buildings have been classified as historic monuments,

including all those in the historic Marais district of the Right Bank. It is against the law to alter the exterior appearance of these buildings.

During the 1960's, much new construction was started throughout Paris. Many new high-rise buildings went up. The 58-story Maine-Montparnasse Tower, France's tallest building, was completed in 1973. But many people believed the construction of high-rise buildings detracted from the city's charm. In 1973, the city council passed a 10-story height limit on new buildings in the heart of the city. High-rise construction shifted to the outskirts of the Paris area.

One of the old facilities removed from Paris was Les Halles, the city's central food market. Its narrow streets and old buildings, in which about 30,000 people worked, could no longer serve the city. In addition, movement to and from Les Halles tied up traffic. The removal was completed in 1974. Most marketing operations were transferred to a wholesale operation at Rungis, a suburb south of Paris. Les Halles was replaced with a shopping and cultural center called Le Forum des Halles. Four of its five levels are belowground.

By the early 1970's, a new 22-mile (35-kilometer) expressway around Paris had been completed. A north-south expressway opened in 1974, and an east-west expressway was completed in late 1976.

A huge, futuristic complex called La Défense opened in 1978 in the western outskirts. It houses offices, shops, entertainment and sports facilities, and apartments. The Arch of La Défense, the centerpiece of the complex, opened in 1989. Another complex, known as La Villette, is located on the northern outskirts of Paris. A museum called the Science and Industry Center, an exhibition hall, and part of a park opened there in the 1980's. A music conservatory was completed there in 1990. Also in 1990, Paris began a renovation of the city's many bridges. A theme park called Disneyland Paris opened in 1992 in the Paris suburb of Marne-la-Vallée, and a second park called Walt Disney Studios opened there in 2002.

Recent developments. By the end of the 1900's, most projects in the vast 1960 renewal plan had been completed as scheduled for 2000. The city took steps to limit air pollution, including placing limits on automobile traffic in Paris. William M. Reddy

Paris, University of, is a government-supported university system in Paris and its suburbs. It consists of 13 units called the University of Paris I, II, III, and so on. The university is coeducational and has over 296,000 students, of whom about 51,000 are from other countries.

The university offers courses in economics, law, liberal arts, science, and many other fields. Each unit specializes in a particular group of subjects. For example, the University of Paris V concentrates on medicine and on pharmaceutical and biological sciences. Students attend lectures and participate in discussion groups.

The University of Paris, one of Europe's oldest universities, was organized during the 1100's. It became known as the Sorbonne, which was the name of its most famous college (see Sorbonne). In 1968, the government passed a law to reform higher education. As a result of this law, the university was reorganized in 1970 into the 13-unit system. P. A. McGinley

Parity, in physics, concerns the symmetry between an event and its reflection in a mirror. The idea of parity is a useful tool in quantum mechanics. Physicists say that *parity is conserved* when an event and its mirror image both satisfy identical laws of nature. In this case, an observer cannot tell the difference between the event and its reflection. The same laws apply to the event and its image, and give the observer no clue by which to identify one or the other. Parity is conserved in all ordinary mechanical and electrical systems.

Physicists once believed that the conservation of parity was a natural law that applied to all events. But in 1956, two Chinese-born physicists, Tsung Dao Lee and Chen Ning Yang, suggested a number of experiments which proved otherwise. The experiments showed that parity was not conserved in a type of nuclear event called a *weak interaction.* An example of such an event is the emission of an electron by a radioactive nucleus.

The first such experiment was performed at the United States National Bureau of Standards (now the National Institute of Standards and Technology) by C. S. Wu of Columbia University and E. Ambler, R. W. Hayward, D. D. Hoppes, and R. P. Hudson of the Bureau, who used atoms of the radioactive cobalt-60. The result of their experiment showed that parity conservation is not a universal law of nature. Chen Ning Yang

Parity, in economics, is equivalence in the values of currencies or in the prices of goods over time. In the United States, the word most commonly refers to agricultural policies aimed at providing farmers with fair prices for their products.

The Agricultural Adjustment Act of 1933 defined the first parity prices. The law calculated the prices at a level intended to give farmers the same purchasing power that they had during the years 1910 to 1914. The *base pe-*

riod of 1910 to 1914 was chosen because it represented a time when American farmers were prosperous. A scale called the *parity index* mathematically compared the prices of goods and services commonly bought by farm families to those same costs during the years 1910 to 1914. The prices farmers received for the goods they sold were compared in the same way to determine the index of prices received by farmers. Prices were said to be "at parity" when these two indexes were equal.

In 1948, the United States Congress created a new parity formula, designed to keep pace with market conditions, that is still used today. Under this formula, the parity price for a product is determined by multiplying the product's average price over the past 10 years by the current parity index. The resulting figure is divided by the index of prices received averaged over the past 10 years. The index of prices received and the parity index are still determined using the 1910 to 1914 base period.

The U.S. government has attempted to provide near-parity prices with such programs as government purchase of products, direct payments to farmers, and acreage allotments (see **Farm and farming** [Federal farm programs]). Some economists argue that increased farm productivity has changed price and cost relationships dramatically since the 1910 to 1914 base period. Thus, they say, parity prices are too high, and overproduction and surpluses have been frequent. Warren F. Lee

Park. Most parks are sections of land set aside for enjoyment by the public. Many parks are used for recreation and to allow visitors to relax in a natural environment. Some parks are used for cultural and educational events, sports, rallies, and festivals. Parks come in many sizes, from a tiny city park less than a block square to national parks containing vast areas of wilderness. Local, state or provincial, and national governments throughout the world administer park systems. Some parks are privately owned and administered but admit the public.

State, provincial, and national parks help preserve the unspoiled beauties of nature. In this picture, a park ranger teaches young campers about Devil's Lake State Park in Wisconsin.

Urban parks contribute natural beauty, greenery, and open space to cities and towns. Queen Elizabeth Park, *above,* is an urban park in the center of Vancouver, British Columbia.

Other parks are not open to the public.

Kinds of parks. There are many kinds of parks. This article describes two main kinds: (1) urban parks and (2) state, provincial, and national parks. For information on theme or amusement parks, see **Amusement park.**

Urban parks provide greenery and open space that add variety to city and town landscapes. Such parks are generally administered by local government bodies. Many urban parks have picnic areas, and some have trails for biking, horseback riding, jogging, and walking. Some parks also have zoos and recreational facilities for basketball, tennis, and other sports. At many lakeside parks, visitors may swim, sail, or canoe. Some parks sponsor classes in such recreational activities as nature study and crafts.

In the United States and Canada, most urban areas have at least one large park and many small parks. Fairmount Park in Philadelphia is one of the largest city parks. It includes a zoo, a theater, an outdoor amphitheater, and six colonial mansions open to the public.

State, provincial, and national parks serve a number of purposes. For example, many national governments set aside land to preserve spectacular mountains or lakes, dense forests, or unusual wildlife. Some parks include geysers, glaciers, or interesting rock formations.

State, provincial, and national governments also preserve areas for their historic value or for recreational use. For example, some parks contain historic battlefields, buildings, or ruins. Many parks offer campgrounds, trails, or skiing areas. Lakes in some parks are used for swimming and other water sports.

The United States has about 5,000 state parks and 50 national parks. Canada has about 1,200 provincial parks and 35 national parks. Its national park system has more land than any other national park system in the world.

History. Historians credit the ancient Sumerians of Mesopotamia with creating the first parks during the

2300's B.C. Many early parks featured hunting areas or elaborate gardens. In general, such parks were developed by wealthy people for their own private use.

The first public parks probably appeared in Greece. By the late A.D. 1200's, small public parks had become common in many European cities. The first public park in colonial North America was established in 1634 in Boston and called Boston Common. The park is still a popular recreational site in downtown Boston. In 1858, work began on Central Park in New York City. Two landscape architects, Frederick Law Olmsted and Calvert Vaux, designed the park. Their attempt to create a rural atmosphere in the park influenced the design of many city parks in the United States.

In 1864, California established the first two state parks in the United States. In 1872, the U.S. Congress passed a bill to establish Yellowstone National Park, the world's first national park. Banff National Park, created in 1885 as Hot Springs Reservation, became the first national park in Canada. In 1916, the National Park Service was established to administer the national parks in the United States. In 1917, Illinois set up the first state agency for managing a state park system. Roger A. Park, Mungo (1771-1806), was a Scottish explorer who led one of the first European expeditions to investigate the course of the Niger River in western Africa. He had an important role in the European exploration of Africa.

Park was born near Selkirk, Scotland. He became a surgeon, but also developed an interest in botany. This interest brought him to the attention of the African Association, a British organization formed to promote exploration of Africa. In 1795, the association sent Park to explore the Niger River. Park reached the Niger near present-day Ségou, Mali, in June 1796. He followed the river a short way and saw that it flowed eastward, not westward as Europeans had thought.

In 1805, Park led a British government expedition to trace the course of the Niger River. Early in 1806, he sailed downstream to the Bussa rapids, now part of Kainji Lake in Nigeria. He drowned there while trying to escape an attack by Africans. Robert I. Rotberg

Park Chung Hee (1917-1979) served as president of South Korea from 1963 to 1979. He had taken power as head of the nation in 1961 after leading a military revolt against the civilian government. In 1979, Park was assassinated by the head of the country's Central Intelligence Agency.

Park, a controversial leader, helped establish many new industries in South Korea, and the country's economy grew rapidly under his rule. On the other hand, Park's government greatly restricted individual rights. For example, the government made it illegal to criticize the president or the constitution, which gave the president almost unlimited power. Park had many people imprisoned for criticizing his policies. He said harsh rule was needed to guard against attack by North Korea.

Park was born in Sonsan-gun, a county in North Kyongsang Province. In the early 1940's, he attended military academies and served in the Japanese Army. He entered the Korean Military Academy in 1945. Park became a Korean Army captain in 1946 and a general in 1953. After leading the 1961 military revolt, he headed a military government for two years. In 1963, Park resigned from the army and was elected president by the voters to head a new civilian government. He was reelected by the voters in 1967 and 1971. In 1972 and 1978, Park was reelected by an electoral college made up of persons loyal to him. Chong-Sik Lee

Parker, Alton Brooks (1852-1926), an American judge and politician, won the Democratic Party nomination for United States President in 1904. He opposed President Theodore Roosevelt, who was running for reelection. The party leaders hoped that Parker, a highly respected conservative, would win the votes of many who were opposed to Roosevelt's progressivism. But Roosevelt's great popularity decisively defeated Parker.

Parker was born in Cortland, New York, and graduated from Albany Law School. He served on several lower state courts in New York. In 1897, he became chief justice of the New York Court of Appeals, the state's highest judicial office. Robert W. Cherny

Parker, Charlie (1920-1955), an alto saxophonist and composer, ranks among the most influential musicians in jazz history. Parker and trumpeter Dizzy Gillespie were responsible for the rise of *bebop,* a complex rhythmic, melodic, and harmonic form of jazz that developed in the 1940's. His many recordings illustrate his amazing technique and the richness of his musical ideas. Several of his compositions, including "Ornithology" and "Confirmation," became jazz standards.

Charles Christopher Parker, Jr., was born in Kansas City, Kansas. He was nicknamed "Bird" or "Yardbird." Parker worked in the bands of Jay McShann, Earl Hines, and Billy Eckstine before forming his own combos in the 1940's. The period from 1944 through 1953 contains the works of his mature style. Parker's improvisations brought new life to a limited number of works that included 12-bar blues, popular songs, a few jazz standards, and compositions based on the harmonies of popular songs. From his youth, Parker was addicted to heroin. His addiction led to many physical and emotional ills during his last years.

Many musicians have learned their craft by imitating Parker's music. A number of the musicians he worked with also influenced the development of jazz. These people include Gillespie, Thelonious Monk, Miles Davis, and Max Roach. Frank Tirro

Parker, Dorothy (1893-1967), was an American poet and short-story writer. She also won fame for her witty conversation and literary criticism.

Most of Parker's verse and stories express a humorous but cynical disappointment with life. She often wrote in a biting, ironic style about the loss of love and idealism. Her precise use of language gives her writing a crisp, conversational tone. One of her most quoted poems, "News Item" (1926), observes that "Men seldom make passes/At girls who wear glasses." Parker's poetry was published in *Enough Rope* (1926), *Sunset Gun* (1928), and *Death and Taxes* (1931). In her short stories, Parker examined the hypocrisy of modern society while show-

ing compassion for its victims. *Here Lies* (1939), a collection of these stories, includes such works as "Mr. Durant" (1924) and "Big Blonde" (1929).

Parker began her literary career in 1916 as a writer for a women's magazine. In 1925, she became one of *The New Yorker* magazine's first regular contributors. She wrote for its book review column for several years. Parker's book reviews were published in *Constant Reader* (1970), a book named for the title of the column.

During the 1920's, Parker belonged to the Algonquin Round Table, a group of famous writers who met regularly at the Algonquin Hotel in New York City. She became known for her quick-witted quips.

Dorothy Rothschild Parker was born in West End (now part of Long Branch), New Jersey, and spent most of her life in New York City. She wrote under her married name, though she divorced Edwin Pond Parker in 1928. Marcus Klein

Parker, Ely Samuel (1828-1895), was the first Indian to serve as United States Commissioner of Indian Affairs. President Ulysses S. Grant appointed Parker, a Seneca Iroquois Indian, in 1869.

Fighting between the Indians and the whites decreased during Parker's term as commissioner, largely because the Indians trusted him. Parker made many enemies among white politicians because he defended Indian rights. His enemies accused him of bribery and fraud. An investigation proved Parker's innocence, but he resigned as commissioner in 1871.

Parker was born in Pembroke, New York, near Batavia. His Indian name was *Do-ne-ho-ga-wa,* which means *Keeper of the Western Door of the Long House of the Iroquois.* His father was a Seneca Iroquois chief, and his mother's ancestors included an Iroquois prophet.

As a young man, Parker studied law. But few Indians of the 1800's were considered citizens, and so New York would not permit him to practice law. He then attended Rensselaer Polytechnic Institute and became a civil engineer. During the American Civil War (1861-1865), he served as General Grant's military secretary. Parker wrote out the terms of the final Confederate surrender, as set forth by Grant. Parker became a brigadier general in 1867. He resigned from the Army when he became Commissioner of Indian Affairs. Beatrice Medicine

Parker, Francis Wayland (1837-1902), an American educator, exerted great influence on modern educational practice. He urged that classrooms be informal and free from old-time strict discipline, and that the child be made the center of the educational process. Parker also developed strong programs of science and geography in the elementary schools. In 1883, he became head of the Cook County (Chicago) Normal School and began teaching his methods to teachers. In 1899, he founded the Chicago Institute. When this school became the University of Chicago's department of education, Parker became the director of the department.

Parker was born in Bedford Township, New Hampshire. He taught in New Hampshire and Illinois. In 1872, he went to Germany to study education. Glenn Smith

Parker, Robert B. (1932-), an American author of detective stories, created the private investigator known only as Spenser. Parker introduced Spenser in the novel *The Godwulf Manuscript* (1974).

Spenser is a tough, wisecracking investigator based in Boston. He works on many of his cases with his friend Hawk. Continuing themes in the series include Spenser's love of cooking; his romance with psychologist Susan Silverman; and his concern with the problems of women and adolescents. These themes set Spenser apart from earlier hard-boiled detectives and influenced many other authors of detective fiction.

Parker has also written detective novels about Jessie Stone, a small-town New England police chief. The series began with *Night Passage* (1997)." Parker's novels have been praised for their excellent dialogue. He was influenced by American author Raymond Chandler, creator of the private investigator Philip Marlowe. Parker completed *Poodle Springs* (1989), a Marlowe novel Chandler had left unfinished at his death. Parker also wrote *Perchance to Dream* (1991), a sequel to Chandler's *The Big Sleep* (1939). Robert Brown Parker was born in Springfield, Massachusetts. Jon L. Breen

Parker, Theodore (1810-1860), was an American Unitarian clergyman and social reformer. He belonged to a philosophical movement called *transcendentalism* (see **Transcendentalism**). Parker was born in Lexington, Massachusetts. From 1837 to 1846, he was pastor of a Unitarian church in West Roxbury, Massachusetts, near Boston. During this period, he caused great controversy by insisting that Christians reject the Bible and religious doctrines and rituals. Parker urged Christians to worship God directly. Unlike the transcendentalist leader Ralph Waldo Emerson, however, Parker did not totally oppose organized religion. In 1841, he stated his views on religion in a sermon called "Discourse on the Transient and Permanent in Christianity." During the 1850's, Parker became one of the leading abolitionists. Parkinson disease is a disorder that gradually destroys cells in certain regions of the brain involved in moving the body. Symptoms include trembling hands, rigid muscles, slow movement, and problems with balance. The disease is named for English physician James Parkinson, who first described the condition in his 1817 work *An Essay on the Shaking Palsy.*

Symptoms of Parkinson disease occur because the condition gradually kills nerve cells that release *dopamine.* Dopamine is a *neurotransmitter,* a chemical that carries messages from one nerve cell to another. Loss of dopamine disrupts communication pathways among nerves that help control movement.

As more cells die, patients have increasing difficulty controlling certain movements. A person with Parkinson disease often walks with a shuffle and finds it hard to write clearly or button clothes. Face muscles may grow rigid, causing a "masklike" expression. Patients may have trouble beginning such movements as rising from a chair. The disease may have psychological effects, including depression and *dementia* (decreased mental ability). The condition may cause serious disability.

Causes. Doctors do not know what causes the most common form of Parkinson disease, which occurs chiefly in people 50 to 70 years old. Some rare forms of the disease that tend to strike people less than 50 years old are caused by defects in *genes* (chemical units of heredity). But research suggests that most cases are not caused by genetic abnormalities.

Parkinson disease due to unknown causes is the most

common form of a group of disorders with similar symptoms called *Parkinsonism.* Other causes of Parkinsonism include certain drugs and exposure to toxic quantities of carbon monoxide.

Treatment with drugs. One of most effective approaches to treatment aims to replace the brain's lost dopamine. Dopamine itself cannot be given as a drug, because it does not cross from the bloodstream into the brain. But a drug called *levodopa* or *L-dopa* does enter the brain, where surviving nerve cells transform it into dopamine. For many patients, L-dopa at first brings dramatic improvement in symptoms. But as the disease progresses, L-dopa becomes less effective in most patients. Many patients also develop troubling side effects, including abnormal movement, sudden changes in muscle control, sleeplessness, vivid nightmares, hallucinations, and confusion. See **Dopamine.**

Drugs called *dopamine receptor agonists* behave somewhat like dopamine in the brain. Dopamine receptor agonists include *pergolide, bromocriptine, pramipexole,* and *ropinirole.* Many patients take these drugs in combination with L-dopa.

Drugs called *anticholinergics* also help control some symptoms, particularly trembling. Still other drugs increase the amount of dopamine available by inhibiting the action of substances that break down L-dopa. Two of these drugs are *tolcapone* and *entacapone.*

Another drug that relieves symptoms, called *selegiline,* has raised interest as a possible means to prevent some of the nerve damage that occurs in Parkinson disease. But studies have failed to produce strong evidence that selegiline slows progression of the disease.

Other treatments. In some cases, doctors may use surgery to destroy particular areas of the brain that produce symptoms of Parkinson disease. Two of these surgical procedures are called *thalamotomy* and *pallidotomy.* Another approach involves implanting a device called a *deep brain stimulation system* that delivers electrical pulses to certain areas of the brain. Researchers continue to explore the possibility of replacing Parkinson patients' lost dopamine-producing cells with transplanted cells from other sources. William J. Weiner

Parkinson's law is a humorous criticism of the administration of business or government. This "law" is based on the idea that "work expands so as to fill the time available for its completion." The law states that the number of administrators increases, whether or not their official responsibilities increase. Such growth supposedly occurs because these officials create assistants. These assistants, in turn, create new work.

C. Northcote Parkinson, a British historian, developed the law in 1957 in his book *Parkinson's Law and Other Studies in Administration.* He applied his law to government administration. But today, people use it to explain almost any situation in which the staff increases faster than the work to be done.

Parkinson supported his law with statistics. For example, he found that the number of administrative officials in the British navy rose 78 percent from 1914 to 1928. But in that period, the United Kingdom reduced its fleet about 68 percent. Critically reviewed by Robert T. Golembiewski

Parkman, Francis (1823-1893), one of America's greatest historians, wrote vivid accounts of the role of the Indians in North American history. He made a famous journey on the Oregon Trail in 1846 and lived with the Indians for months to gather material for a book. Published in 1849 as *The California and Oregon Trail,* it later became famous as *The Oregon Trail.* Parkman also made a thorough study that included five trips to Europe for material before he published *History of the Conspiracy of Pontiac* (1851).

He also wrote *France and England in the New World,* a seven-volume series. These books described the history of the struggle between France and Britain for control of North America, and the part the Indians played in it. The series included *Pioneers of France in the New World* (1865), *The Jesuits in North America* (1867), *The Discovery of the Great West* (1869), and *Montcalm and Wolfe* (1884). Parkman's books did not include the economic elements of history now considered important, but they were so realistically written that they still may be read with great pleasure.

Parkman's health had been damaged by the hardships of his trip on the Oregon Trail. He lost much of his sight, but continued his work with the help of a reader. Parkman studied horticulture as a hobby and was so successful that he became a professor of horticulture at Harvard University in 1871.

Parkman was born in Boston. He graduated from Harvard University and later studied law there. He was elected to the Hall of Fame for Great Americans in 1915.

Parks, Rosa Louise (1913-), an African American civil rights activist, is best known for her role in a 1955 boycott of the Montgomery, Ala., bus system. Parks triggered the boycott when she refused to give up her seat to a white passenger on a bus. Her action helped bring about the civil rights movement in the United States.

Parks was arrested for violating a city law requiring that whites and blacks sit in separate rows on buses. She refused to give up her seat in the middle of the bus when a white man wished to sit in her row. The front rows were for whites only. The law required blacks to leave their seats in the next rows when all seats in the front rows were taken and other whites still wanted seats.

Even before Parks's arrest, Montgomery's black leaders had been discussing a protest against racial segregation on the city's buses. Parks allowed the leaders to use her arrest to spark a boycott of the bus system. The leaders formed an organization to run the boycott. Martin Luther King, Jr.—then a Baptist minister in Montgomery—was chosen as president.

For 382 days, from Dec. 5, 1955, to Dec. 20, 1956, thousands of blacks refused to ride Montgomery's buses. Their boycott ended when the U.S. Supreme Court declared segregated seating on the city's buses unconstitutional. The boycott's success encouraged other mass protests demanding civil rights for blacks.

Parks was born in Tuskegee, Ala. She attended Ala-

bama State Teachers College. She held a variety of jobs and, in 1943, became one of the first women to join the Montgomery Chapter of the National Association for the Advancement of Colored People (NAACP). She served as the organization's secretary from 1943 to 1956.

Parks lost her job as a seamstress as a result of the Montgomery boycott. She moved to Detroit in 1957. From 1967 to 1988, she worked on the Detroit staff of John Conyers, Jr., a Democratic member of the U.S. House of Representatives. In 1979, she won the Spingarn Medal for her work in civil rights. She wrote an autobiography, *Rosa Parks: My Story* (1992). In 1999, she was awarded a Congressional Gold Medal.

Parliament is the national lawmaking body of the United Kingdom, Canada, Australia, Japan, and other democratic countries. Some parliaments are made up entirely of elected representatives. Others have both elected and appointed or hereditary members.

A parliamentary government differs from the system of government in the United States, where the president and vice president are elected separately from Congress. In a parliamentary government, the top officials are known as *ministers* (heads of government departments). The ministers make up an executive body that is called the Cabinet. They are also members of parliament, and so they carry out legislative functions as well. The top officials are elected by the voters of the district that they represent, rather than by the entire nation. However, the Cabinet functions under the control of the parliament as a whole. The Cabinet remains in power only as long as it has the support of a majority of the members in parliament.

In most countries with parliamentary government, the chief executive is called the *prime minister.* The prime minister is the leader of the largest party in parliament or of a *coalition.* A coalition is a temporary joining of parties that together have a majority of seats. The prime minister is formally appointed by the official head of state. The official head of state may be the king or queen of a monarchy or the president of a republic. In most parliamentary governments, the prime minister chooses members of his or her own political party to become ministers. The most important ministers belong to the Cabinet. Parliamentary government is also called *Cabinet Government,* because control rests with the Cabinet.

Members of parliament are elected to a maximum term of office. At the end of the term, an election must be held. But a general election may occur at any time short of a full term. For example, the Cabinet may resign and a new election be held if parliament defeats a program the prime minister considers essential. An election also must occur if parliament votes "no confidence" in the Cabinet.

The British Parliament

Unlike the Congress of the United States, the British Parliament does not obtain its authority from a written constitution. Instead, Parliament's power developed gradually over many centuries and is based on tradition and custom as well as written law.

Parliament consists of the *monarch* (king or queen); the House of Commons, which is often called simply the *Commons;* and the House of Lords, which is often called the *Lords.* But in daily conversation, the term *Parliament* means just the Commons and the Lords. The power of the Commons greatly exceeds that of the monarch or of the Lords. Although the monarch officially has the power to reject legislation passed by Parliament, no British ruler has done so since the early 1700's.

The House of Commons is the real governing body of the United Kingdom, though it is called the *lower house* of Parliament. The term *lower house* refers to the branch of a lawmaking body considered closer to the people. The House of Commons, like nearly all other lower houses, consists of representatives who are elected by popular vote.

The House of Lords may delay, but not defeat, legislation passed by the Commons. Money bills passed by the Commons become law within one month, even without approval of the Lords. Nonmoney bills passed by the Commons in two consecutive sessions automatically become law a year after the second passage.

The House of Commons has 659 members—529 from England, 40 from Wales, 72 from Scotland, and 18 from Northern Ireland. The prime minister and most Cabinet

ministers are members of the Commons. Each member represents a voting district called a *constituency.* Members are not required to live in the constituency they represent. Clergy of the Church of England, the Church of Scotland, the Church of Ireland, and the Roman Catholic Church cannot be elected to the Commons. Members of the House of Lords and certain government officials also are ineligible. Members of the House of Commons receive an annual salary. They also get travel and administrative expenses.

How members are elected. Members of the Commons are chosen in a *general election,* in which all voters may take part. If a member dies or resigns, the constituency chooses a new representative in a *by-election.*

Members of the House of Commons are elected to a maximum term of five years, after which Parliament must be dissolved and another election held. But an election may be called at any time, and most Parliaments *sit* (are in session) for less than five years. The prime minister may call for a new election if Parliament refuses to support the Cabinet's policies. The prime minister also may call for a vote if he or she believes the country's political climate favors another victory by his or her party.

How the House of Commons works. The House of Commons sits for about 160 days annually from November to October. Most sessions last from midafternoon to evening, though some continue through the night.

The Commons meets in a long room with rows of benches running along two sides. The Speaker of the House of Commons sits at one end of the chamber. The Speaker presides over the sessions, grants members the right to speak, and keeps order during debates. Members of the prime minister's party, representing the *Government,* sit on the benches to the Speaker's right. Members of other political parties supporting the Government also sit on that side of the room. Members of the second largest party, called the *Opposition,* and their supporters sit to the left of the Speaker. The leaders of the Government and the Opposition are known as the *front bench* because they sit on the benches nearest the center of the chamber. Other members sit behind them and are known as the *back bench.*

The Government and the Opposition debate most proposed legislation. Other discussion between the two sides takes place at the question periods at the opening of the order of business. Members of the Opposition question the prime minister and other members of the Government about their policies.

The House of Lords is called the *upper house* of Parliament, though it has less power than the House of Commons. The term *upper house* refers to the branch of a lawmaking body that is less subject to control by the voters. This house, for example, is not an elected assembly. Most of its members are honorary appointees.

The main function of the House of Lords is to review legislation passed by the House of Commons. Although the Lords can amend bills, it rarely changes their basic principles. The Lords also serves as the United Kingdom's highest court of appeals.

The House of Lords has about 700 members, including 92 *hereditary peers and peeresses,* about 600 *life peers and peeresses,* and 26 *lords spiritual.* Hereditary peers and peeresses are members of the nobility who have inherited their titles. In 1999, reforms went into effect that limited the number of hereditary peers or peeresses in the House of Lords. Life peers and peeresses are appointed to the Lords to honor their achievements in business, civil service, or other fields. They have the title of baron or baroness. The life peers and peeresses include about 30 *law lords,* also called *lords of appeals,* who are chosen from among the United Kingdom's highest-ranking judges. They form the final court of appeal for civil cases throughout the country and for criminal cases in England, Wales, and Northern Ireland. Lords spiritual are senior members of the Church of England. Life peers, law lords, and lords spiritual are appointed to their seats for life. Their children do not inherit their titles.

The Lords Chamber, where the House of Lords meets, was first occupied in 1847. The cushioned benches on the left form the main seating area for Government members, and the benches across the aisle are for the Opposition members.

Members of the House of Lords are not paid a salary. However, they do receive travel expenses.

The Houses of Parliament. Parliament has met on the same site in London since 1547. For nearly 300 years, it met in St. Stephen's Chapel in the Palace of Westminster. A fire destroyed that building in 1834. The present Houses of Parliament were completed in 1860. Like the old building, they are known officially as the Palace of Westminster. In 1941, during World War II, a German bomb demolished the meeting chamber of the House of Commons. The present chamber was finished in 1950.

History. The British Parliament developed from a council of nobles and high-ranking clergy that advised the early kings of England. After the Norman Conquest in 1066, this informal advisory group became a formal assembly called the Great Council. It met three times yearly to help the king decide matters of government policy and to make laws.

During the early 1200's, King John began to call knights elected from the *shires* (counties) to some meetings of the Great Council. He summoned the knights to obtain their approval of taxes he had levied, because tax collection would be difficult without their cooperation. In the mid-1200's, the English statesman Simon de Montfort enlarged the council, by then called Parliament, to include elected representatives from towns, shires, and boroughs. The meeting King Edward I called in 1295 became known as the *Model Parliament,* because it resembled later Parliaments.

By the mid-1300's, the elected representatives began to meet separately from the nobles and bishops, and Parliament was divided into two houses. By the late 1300's, the Commons obtained the right to consider tax legislation before it was discussed by the Lords. But the Commons had no power to initiate legislation. It could only ask the monarch to grant requests. By the early 1400's, the Commons gained the right to introduce bills.

Parliament gains strength. As its role in government increased, Parliament demanded greater power. During the 1620's, the struggle between Parliament and the king became bitter. In 1628, Parliament forced King Charles I to sign the Petition of Right, a document that limited royal power. However, Charles refused to obey the agreement. He did not allow Parliament to meet from 1629 until 1640, when he was forced to call a meeting to obtain funds. But Parliament refused to provide any money unless Charles obeyed the Petition of Right. He refused, and civil war broke out. In 1649, Parliament ordered Charles beheaded. The legislature, led by the Puritan general Oliver Cromwell, declared England a republic and ruled until 1653. Because the same Parliament had remained in session since 1640, it became known as the *Long Parliament.* Cromwell then ruled as a dictator until his death in 1658. In 1660, a new Parliament restored the monarchy.

The Bill of Rights of 1689 gave Parliament the right to meet frequently and have freedom of speech during debates. It also confirmed the right of the Commons to control financial legislation. By the early 1700's, Parliament had gained almost total control over the monarchy. In 1707, the Act of Union joined England, Scotland, and Wales together to form the Kingdom of Great Britain. The act established a single national parliament.

During the 1800's, the membership of Parliament changed dramatically. In the early 1800's, nobles and other wealthy landowners controlled most of the members of Parliament, including the House of Commons. Some districts with almost no voters had representation, while districts with large populations had none. Few citizens had the right to vote. In 1832, Parliament passed a reform act that distributed seats on the basis of population. The act also reduced the property requirements for voting to give most middle-class men, but no women, the right to vote. The Reform Acts of 1867 and 1884 extended the vote to nearly all adult males. In 1928, women received full voting rights.

The decline of the House of Lords. During the 1800's, the two houses of Parliament remained nearly equal in power. Although the Commons had control over money bills, the Lords had the power to veto legislation. In 1909, the Lords rejected a budget approved by the Commons. A struggle broke out between the two houses of Parliament, which resulted in the Parliamentary Act of 1911. Under this act, the House of Lords lost its veto power. The Lords was permitted to delay money bills for only one month and nonmoney bills for two years. The Parliamentary Act of 1949 reduced to one year the length of time that the Lords could postpone nonmoney bills. In 1999, legislation abolished the right of hereditary peers to inherit a seat in the Lords along with their title. Ninety-two hereditary peers, most of whom were elected by other hereditary peers or by the full House of Lords, were to continue to serve in the Lords until further reform of the house was completed.

Parliaments in other countries

The parliaments of Canada, Australia, and New Zealand greatly resemble the British Parliament. The Canadian Parliament has two houses—the Senate and the House of Commons. Senators are appointed and have less power than do the elected members of the House of Commons. The Parliament of Australia, called the Federal Parliament, is made up of the Senate and the House of Representatives. Members of both houses are elected. Most bills are introduced in the House of Representatives, which has more power than the Senate does. The New Zealand Parliament consists of one house, the House of Representatives, whose members are elected. India, South Africa, and many other former British colonies also have parliaments.

The parliament of Germany consists of the Bundestag, an elected assembly, and the Bundesrat, whose members are appointed. Japan's parliament, which is called the Diet, has two elected houses. The Althing of Iceland, the world's oldest parliament, has existed since A.D. 930.

Parliamentary procedure is a way to conduct a meeting in an orderly manner. Parliamentary procedure, also known as *rules of order,* helps the presiding officer keep order during a meeting as well as guide participants in transacting business. The procedure is called *parliamentary* because it comes from the rules and customs of the British Parliament. By the end of the 1600's, the broad principles had become well established. As actual procedures developed, they became the basis for deciding later questions of parliamentary law. In 1876, Major Henry M. Robert, a United States Army Engineer, wrote what became the most popular book on parliamentary procedure, *Robert's Rules of Order.*

Any group that conducts its meetings according to parliamentary rules will encounter questions about the proper procedure to be used. To answer such questions, the group should consult *Robert's Rules of Order* or another standard authority on parliamentary procedure. All such authorities tend to follow the same general principles, but they may differ on specific points. Thus, an organization should adopt a single authority for consistency.

Any system of parliamentary procedure should be both democratic and efficient. To ensure democracy, the rights of the minority must be protected and all members of the group must be able to discuss a matter before the majority disposes of that matter. To be efficient, the procedure must assist the group with a minimum of confusion and delay. It must also ensure that all members are aware of the substance and implications of each matter considered.

Forming an organization

A group that wishes to form an organization first calls a meeting of those who may be interested. At this meeting, a temporary organization is established. The group selects an acting presiding officer and an acting secretary, who begins keeping a record of the business transacted. The members then elect a temporary presiding officer and a temporary secretary, who serve until the organization is established permanently and permanent officers are elected.

Bylaws. Before a group officially becomes a permanent organization, it must prepare a set of *bylaws.* The bylaws can be prepared by a committee elected by the organization or appointed by the temporary presiding officer. The bylaws may be adopted as suggested by the committee, or they may be changed through the process of discussion and voting.

The bylaws should define the characteristics of the organization and describe how the organization will operate. They should also include any rules that the organization considers sufficiently important to require prior notice and a large majority for changing. These rules cannot be suspended except as provided for in the bylaws.

Adoption of the first set of bylaws requires a majority vote by the members of the organization. Upon adoption, the bylaws immediately go into effect. As soon as possible, all members should be provided with a copy, as well as copies of other pertinent documents.

Officers. The essential officers for any organized group are a president and a secretary. If the members pay dues or raise money for the organization in any way, a treasurer is also necessary. Some groups have an officer who serves as both secretary and treasurer.

The president (1) presides over all meetings, (2) supervises the work of other officers and committees, (3) represents the organization, and (4) appoints committees if the bylaws grant the officer this power.

The secretary (1) notifies members of scheduled meetings, (2) keeps and reads the minutes, and (3) handles correspondence.

The treasurer (1) handles all the organization's finances, (2) keeps a record of income and expenses, and (3) helps prepare the annual budget.

Other officers. Many organizations, especially if they are large or carry on extensive activities, have additional officers. These usually include a *vice president,* who aids the president and takes the president's place when that officer is unable to perform the duties of the position. An organization may divide the secretary's job between a *recording secretary,* who keeps the minutes and other records, and a *corresponding secretary,* who handles all letter-writing. Some clubs elect a *historian,* who keeps a permanent record of activities and members, and a *sergeant at arms,* who maintains order during meetings. A club might also have a *parliamentarian.* The parliamentarian advises the president on matters of procedure.

Electing officers. Most organizations elect officers once a year. There are two methods of nominating officers. Under the first method, the group chooses a nominating committee to propose one or more candidates for each office. After the committee makes its nominations, other candidates may be nominated *from the floor* (by the members attending the meeting). Under the second method, the presiding officer declares that "nominations are in order." He or she then accepts nominations from the floor for each office.

A vote for officers, like votes on other business matters, may be held (1) by a show of hands or (2) by secret ballot. There are fewer risks of embarrassing any of the candidates when the members vote by secret ballot. In addition, the candidates do not have to leave the room during the voting. If only two candidates are nominated for an office, one must receive a majority of the votes to win. Usually, if three or more are nominated, the one who receives a *plurality* (the most votes) wins. But the bylaws may require that a candidate must receive a majority vote to be elected. In such cases, the winner would be chosen in a run-off election between the two candidates with the most votes.

Committees handle many duties that a group's officers do not or cannot perform. They also do jobs that cannot be done by the entire membership at regular meetings. Most organizations have two types of committees: (1) standing committees and (2) special committees.

Standing committees deal with regular and continuing matters, such as membership and finance. These committees are usually selected after each annual election, and they *stand* (remain active) through the year.

Special committees may be selected at any time to deal with specific matters. This committee might be appointed to plan a social event, to revise the group's bylaws, or to nominate new officers. The special committee ceases to exist after it completes its assigned task.

Bylaws usually state whether standing committees shall be appointed or elected. If they are to be appointed, the president names the members of each committee. The president usually creates special committees and appoints their members. Organization members can also create special committees by voting to do so. Each committee should have an odd number of members, in order to avoid tie votes on committee decisions. The president may select one of the committee members to be chairperson, or the committee may elect its own chairperson. He or she participates in the discussion and voting. Committees do not have to follow the rules of parliamentary procedure. Thus, their meetings are usually informal discussions.

Holding meetings

A meeting officially begins when a *quorum* is present and the presiding officer calls the group to order. A quorum is the minimum number of members who must be present in order for the organization to transact business. In most organizations, a majority of the membership must be present in order to have a quorum. But a group's bylaws can name any part of the total membership as a quorum.

Order of business. If the organization's bylaws do not prescribe an order of business, there is a series of steps that are commonly accepted: (1) call to order at the appointed meeting time with a quorum present; (2) read, correct, and approve the minutes of the previous meeting; (3) hear reports of officers; (4) hear reports of boards; (5) hear reports of standing committees; (6) hear reports of special committees; (7) consider unfinished business; (8) consider new business; (9) hear announcements and requests that require no formal action; and (10) adjourn.

Minutes. The secretary's minutes should be an accurate record of all the organization's actions. At the start of each meeting, the secretary reads the minutes of the previous meeting so the members can recall the actions taken. The minutes do not summarize the discussions that take place during the meeting. They simply state the actions proposed, and what the organization decided to do about each one.

In most organizations, the secretary records the minutes in a book. Each set of minutes begins with the date and place of the meeting, the time the meeting began, and the name of the presiding officer. Some groups call the roll at the beginning of each meeting, and include a list of the members present in the minutes.

After the secretary has read the minutes, the president asks whether any member wants to make any corrections or additions. If so, the group must vote on each correction or addition. The president then asks for approval of the minutes. In some organizations, a member must propose that the group approve the minutes. But the simplest way is for the president to state that if there are no objections, the minutes will be considered approved. The secretary notes the approval and the date at the end of the minutes.

Motions. A *motion* is a brief, precise statement of a proposed action. A member can make a motion only when that member has been recognized by the presiding officer and *has the floor*—that is, has been given permission to speak. Some motions require a second before they can be discussed by the group. The act of seconding does not commit that member to supporting the motion. It signifies that member's interest in having the motion considered. After a motion has been made and seconded, the presiding officer restates the motion for the benefit of the rest of the members. In the case of a complicated motion, the secretary may be asked to read the motion from the minutes. The members then debate the motion. Perhaps the members want to *amend* (change) the motion in some way. If so, they must propose and *pass* (approve) a new motion amending the original motion. They must then debate the original motion as amended.

Debate on a motion usually continues until each member who wants to speak has done so. But the members can end the debate at any time by passing a motion to have the group vote immediately. To do so, a member would *move the previous question.* The members can also pass a motion to set a time limit on the debate. In legislative bodies, this rule of parliamentary procedure is known as *cloture.* See **Cloture**.

Each motion must be resolved of in some way before the group can take up another item of business. If the members want to postpone action on a motion, they may vote to "table the motion." The presiding officer or the group may dispose of a motion temporarily by referring it to a committee. The committee investigates the matter and presents a report at a later meeting. The group then decides what action it wants to take on the motion. Eventually, all motions must be either approved

Terms used in parliamentary procedure

Adjourn means to end a meeting.
Agenda is a list of items to be considered at a meeting.
Appeal is a request for a majority vote to overrule a decision of the presiding officer.
Chairman pro tempore is the temporary chairman.
Decorum in debate, *duh KOH ruhm,* refers to the observance of normal rules of courtesy and proper procedure while discussing motions.
Dilatory motion, *DIL uh TOH ree,* is a meaningless motion. The presiding officer must rule it out of order.
Division is a count of votes by a show of hands.
Gavel is a small wooden hammer. The presiding officer of an organization uses it to call meetings to order and to quiet disorder during the meeting.
Order of business is the series of steps covered in a meeting, from the call to order through adjournment.
Pending question is the motion under consideration.
Plurality is the largest number of votes received by any candidate in an election involving three or more candidates.
Point of order is an objection raised by a member because of improper procedure or annoying remarks. It must be ruled upon immediately by the presiding officer.
Question of privilege is a request that is made by a member who asks the presiding officer to deal with an emergency, disorder in the assembly, or other matters of general or personal welfare.
Ratify refers to a motion to approve an action already taken, such as a ruling by the presiding officer.
Recess is a temporary interruption of a meeting.
Unanimous consent refers to a request by the presiding officer on matters where differences of opinion are not expected. If there is an objection, a vote must be taken.

or disapproved by a majority of the membership.

Voting on motions takes place when there are no more requests to speak on a motion, or after debate has ended. First, the presiding officer restates the motion or has the secretary read it. Then the presiding officer calls for a *voice vote.* All in favor of the motion say "aye," then all those opposed say "nay." If the presiding officer cannot tell which side has the majority, he or she can ask supporters or opponents of a motion to stand or to hold up a hand.

The bylaws may require a *roll-call vote* on certain types of motions. A *secret ballot* is usually taken when electing officers and as required by the bylaws. A *majority vote* is more than half of the legal votes cast unless otherwise defined in the bylaws.

The presiding officer has the right to vote on all issues but usually only votes when that vote would change the result of the vote by the members. The presiding official may vote to break a tie vote. If the nay votes total one less than the aye votes, the presiding officer may cast a nay vote in order to create a tie vote and thus defeat the motion.

Parliamentary procedure does not have to be complicated and mysterious. As long as the presiding officer conducts meetings fairly and judiciously, and members learn the basic principles and procedures of parliamentary procedure, business can be transacted democratically and efficiently. Parma, *PAHR muh* (pop. 170,520), is a city in northern Italy. It lies about 75 miles (121 kilometers) southeast of Milan. For the location of Parma, see **Italy** (political map). Parma dates from the period of the Roman Republic (509 B.C. to 27 B.C.). It has many art treasures. Its cathedral dates from the 1000's. The building is an example of Lombard-Romanesque architecture. Its dome has a fresco, *Assumption of the Virgin,* by the artist Correggio (see **Correggio**). The University of Parma was founded in 1502. The area around Parma is famous for Parmesan cheese. Anthony James Joes

Parmenides, *pahr MEHN ih deez* (515?-450? B.C.), was the most important of the early Greek philosophers who lived before Socrates. Parmenides expressed his philosophy in a poem, *On Nature.* The complete poem has not survived, but large parts have been preserved.

Unlike previous Greek philosophers, Parmenides did not explain the origin of the world in terms of material substances, such as air or water. Instead, he deduced the nature of reality from logical arguments. Parmenides first argued that *what is not* is a notion that cannot properly be thought of or spoken of. Then he argued that if we eliminate *what is not* from our description of reality, *what is* turns out to be far different from what our senses tell us. Instead of a world made up of many changing things, *what is* is just one thing—unchanging, perfect, and without beginning or end. Parmenides was born in Elea, a Greek colony in Italy. Carl A. Huffman

Parnassus, *pahr NAS uhs,* is a mountain in Phocis in Greece. Its twin peaks rise to more than 8,000 feet (2,400 meters). In ancient times, Parnassus was considered one of the most sacred Greek mountains. It was described as a favorite place of the gods Apollo, Pan, and Dionysus and the goddesses called the Muses. The famous oracle of Delphi was located on its lower slope. Nearby was the Castalian spring. It was supposed to inspire those who drank from it to write poetry. Justin M. Glenn

Parnell, Charles Stewart (1846-1891), an Irish political leader, almost obtained *home rule* (self-government) for Ireland by constitutional means (see **Home rule**). But scandal ruined his career.

Parnell entered the British House of Commons in 1875 as a member for County Meath. He united Ireland's Home Rule Party, and tried to make it powerful by obstructing all other legislation until Irish demands were met. To unite Ireland, Parnell came to terms with Irish revolutionaries and supported the Land League. The league wanted land reforms that would result in tenant farmers owning their farms.

Charles Parnell

In 1879, Parnell visited the United States and collected large amounts of money for the Land League. When he returned to Ireland, he suggested boycotting the landlords to force land reform. For this policy and for trying to obstruct legislative proceedings, Parnell was arrested and imprisoned for six months. From prison, he urged tenant farmers not to pay rent. After his release in 1882, Parnell returned to Parliament and tried again to force home rule. For a time, he seemed about to succeed. In 1886, Parliament passed the Tenant's Relief Bill, which improved farmers' conditions.

But the next year, Parnell had to defend himself against charges that he was involved in the Phoenix Park murders. Irish terrorists had committed these murders in 1882. Parnell proved that letters which seemed to implicate him were forgeries.

In 1889, just as Parliament was about to meet, a political supporter of Parnell named Captain William O'Shea filed divorce proceedings against his wife because of her relationship with Parnell. The charges were proved, and Parnell's reputation and influence were ruined. Parnell married Katharine O'Shea after the divorce and lost his position as leader of the Home Rule Party. He later tried unsuccessfully to regain his political leadership.

Parnell was born on his family's estate of Avondale in County Wicklow. He was educated at Magdalene College of Cambridge University. Thomas E. Hachey

Parochial school, *puh ROH kee uhl,* is a private school conducted and supervised by a religious group. Many people think the term *parochial* means schools conducted by the Roman Catholic Church. But *parochial* comes from the Latin word for *parish* (church district) and refers to a school operated by any church. The name usually applies to elementary and high schools, but can also describe colleges and universities. Instruction in parochial schools includes religious education as well as many of the subjects taught in public schools. In the United States, parochial schools are the only schools allowed by law to require that teachers and staff hold particular religious beliefs.

The Roman Catholic school network grew rapidly in the 1800's and 1900's, becoming the largest parochial school system in the world. Registration in U.S. Catholic schools peaked in the mid-1960's, when 5 $\frac{1}{2}$ million students were enrolled. In the Roman Catholic system, a superintendent appointed by the bishop directs the parish schools. Many high schools are cooperatively directed and supported by several different parishes.

Protestant groups also operate a number of parochial schools. Many Protestant schools are *parent-controlled*—that is, run by an independent board of elected parents or association members, under the supervision of a congregation or religious body. Protestant denominations that administer schools include Baptists, Lutherans, and Episcopalians. In the late 1900's, schools run by evangelical Protestant groups grew rapidly. The Association of Christian Schools International is a large group representing a number of evangelical denominations. This association oversees several thousand schools, including more than 100 colleges.

The largest system of Jewish schools in the United States is the National Society for Hebrew Day Schools, also called Torah Umesorah. This society operates Orthodox schools. The Solomon Schechter Day School Association oversees conservative Jewish schools. Many other Jewish groups also maintain parochial schools.

Parochial schools operate with funds provided by the religious groups that administer them. Many such schools also charge students a fee called *tuition*. Some supporters of parochial education feel that parochial schools, like public schools, should also receive tax dollars. They argue that parochial education is a form of school choice for which parents should be given tax subsidies or credits. But the Supreme Court of the United States has ruled several times that laws providing tax funding for parochial education are unconstitutional. These rulings held that such funding violates the constitutional principle of separation of church and state because the schools endorse particular religious beliefs.

A related debate concerns whether parochial schools should be allowed to participate in a school choice plan called a *voucher system*. In a voucher system, families receive coupons called *vouchers*. Parents can use their vouchers to pay for their children to attend any public or private school in the program. Because vouchers are funded with taxes, some people feel that including parochial schools in voucher systems also violates the principle of separation between church and state. But in 2002, the U.S. Supreme Court ruled that voucher programs can include parochial schools without violating the Constitution of the United States. Stephen M. Fain

Parody is a comic imitation of a literary work. A writer creates a parody to ridicule the work of another by exaggerating that author's style or ideas. Parody is in literature what a cartoon is in art.

Parodists usually choose famous writers who have a distinctive style, so that the reader can easily recognize the subject of the parody. For example, the American authors Ernest Hemingway and Henry James have often been parodied. Parodists exaggerate Hemingway's crisp style and James's complicated sentences.

Expert parodists thoroughly know the subject they are parodying. A successful parody demonstrates not only the understanding of the original author but also the parodist's own skill. Although parody involves criticism, it is also a kind of appreciation. By selecting a certain author, the parodist acknowledges that the subject is both original and well known.

Many early English novelists began their careers as parodists, including Jane Austen, Henry Fielding, and William Makepeace Thackeray. Perhaps the leading American parodist of the mid-1900's was Peter De Vries. Almost all his novels have passages in which he parodies the work of others. H. George Hahn

Parole is the early release of criminals from prison, in most cases as a reward for good behavior. A prisoner can be paroled only after serving part of his or her sentence. Parole is actually a continuation of a sentence away from prison, and paroled prisoners, called *parolees,* must follow certain rules. For example, they must get a job, support their family, and avoid liquor and other drugs. If parolees violate any of the rules, or if they commit another crime, they may be sent back to prison.

A parole board decides whether a criminal should be released. In the United States, parole boards are part of most state governments. A board considers such factors as the crime involved, the time already served, and the criminal's behavior in prison. Parolees are supervised by a parole officer for a certain period, depending on the sentence and the time served.

Parole has several purposes. Some criminal justice officials believe parolees have a better chance of becoming law-abiding citizens than criminals released without supervision. Parole also tries to protect society by preventing offenders from committing new crimes. Parole also costs society less than keeping people in jail.

In the late 1900's, many criminologists joined in criticizing parole. They believed it did not help prisoners readjust to society. They also thought the main purpose of prison should be to punish criminals, not to reform them. These critics charged that the parole system is unfair because criminals who commit the same crime may not have to spend the same length of time in prison. Some may be paroled sooner than others. By 1980, a number of states had abolished parole and substituted *fixed sentences*. Under this system, criminals must serve a specific amount of time in prison, depending on their crime. In 1984, Congress passed a law that abolished parole for federal prisoners.

Parole differs from probation. A judge may place a criminal on probation instead of sending him or her to prison. Criminals are paroled only after they have served time in prison. See **Probation**. James O. Finckenauer

Parris Island Marine Corps Recruit Depot, South Carolina, trains most United States Marine Corps recruits east of the Mississippi River. It also trains all women Marine recruits. The island, near Beaufort, covers 7,100 acres (2,900 hectares). Horse Island Bridge and causeways connect the island to the mainland. Alexander Parris, public treasurer of South Carolina in the 1700's, once owned the island. The Marines established their first post there in 1891.

Parrish, Maxfield (1870-1966), an American painter and illustrator, portrayed a world of rich color and poetic fancy. His travels in Italy and his later life among the New Hampshire mountains developed his love for romantic, idealized natural beauty. The towering peak of Ascutney, within sight of his home, is suggested in many of his works. An unusual shade of blue, which Parrish used in many of his pictures, came to be known as "Maxfield Parrish blue."

Parrish's posters, magazine covers, murals, and other decorations demonstrate his skillful draftsmanship and distinctively elegant style. The many books he illustrated include *Mother Goose in Prose, Knickerbocker's History of New York, The Arabian Nights, Wonder Book, Poems of Childhood, Golden Age,* and *Dream Days.* The rich and glowing colors that Parrish used in his works attracted many admirers.

Parrish was born in Philadelphia of Quaker parents. He graduated from Haverford College and later studied at the Pennsylvania Academy of the Fine Arts. He also studied under Howard Pyle at Drexel Institute of Art, Science and Industry (now known as Drexel University).

Parrot is the name of a large group of colorful birds found chiefly in warm, tropical regions. They are popular as pets because they become affectionate and tame, and many can be taught to talk. Parrots range from about 3 inches (8 centimeters) to over 3 feet (90 centimeters) long. Most parrots have thick, hooked bills, and many have long tails. Parrots also possess short legs and feet with two toes pointing forward and two pointing backward. This arrangement of the toes is called *zygodactyl* (pronounced *zy guh DAK tuhl*). These strong, grasping feet enable parrots to grasp fruits and nuts, climb, and even hang acrobatically from tree branches. *Parakeet* is a general name for many kinds of small to medium-sized parrots, especially those with long, pointed tails.

Parrots are noisy, sociable birds that live chiefly in forested areas. Some parrots live in *savannas* (grassy, thinly wooded areas) and deserts. Parrots commonly eat fruits, nuts, seeds, and buds. Some also eat nectar and pollen.

Most parrots choose one mate for life. Female parrots lay round, white eggs. They deposit the eggs in holes in trees, on the ground, in cracks in rocks, or in holes dug in termite nests. The *monk parakeet* of Argentina builds a huge community nest out of sticks. Many pairs of monk parakeets share the nest, which provides a safe place to lay eggs and also protects the birds from cool weather. Other parrots may nest in artificial nest boxes placed in trees by people.

Kinds of parrots. There are about 350 species of parrots. About half live in Central and South America. Most of the rest live in Australia, New Guinea, and nearby Pacific islands. About 50 species live in Africa and southern Asia. The United States once had its own species of parrot, the *Carolina parakeet,* but it became extinct in about 1920 because of hunting and forest destruction. A rare species, the *thick-billed parrot,* lives in western Mexico and may wander into southern Arizona and New Mexico. The *Puerto Rican parrot* is an endangered species.

Parrots of South and Central America. The *macaws* are large parrots that live mainly in tropical lowland forests of South America. A few species live in Central America. Macaws have long, pointed tails and huge bills. The blue *Hyacinth macaw* is the world's largest parrot. It grows up to 39 inches (100 centimeters). *Amazons* are predominantly green parrots with big, chunky bodies and short, squared tails. Colorful spots adorn their wings and head. These birds live in treetops in the tropical forests. *Parakeets* and *conures* are small to medium-sized, mainly green parrots with long, pointed tails. *Parrotlets* are tiny parakeets with short tails.

Parrots of Australia and New Guinea. Cockatoos live in Australia, New Guinea, and nearby islands. They have large, thick bills. Most cockatoos are white with bushy crests of feathers on their heads. The *palm cockatoo* is a large, jet-black bird. It has a bare skin patch on its cheek, which may turn bright red when the bird is alarmed. The rose-colored *galah (guh LAH)* lives in large flocks in central Australia. The *cockatiel,* a long-tailed relative of cockatoos, commonly inhabits northern and central Australia.

Lories and *lorikeets* live mainly in wet forests in New Guinea, Australia, and nearby islands. They are small- to medium-sized parrots with black, red, or orange bills. Their bills are the longest and narrowest of any parrot, and they have brush-tipped tongues for gathering pollen and nectar. The tiny *pygmy parrots* of New Guinea have extremely long toes. They creep up tree trunks, like small woodpeckers, in the thick forest. The *budgerigar (buhj uhr ee GAHR),* from central Australia, is the best-known parakeet because of its popularity in zoos and as pets. The *rosellas,* found in coastal Australia, have bold patterns of blues, reds, and yellows on their bodies.

Parrots of New Zealand include some of the most unusual species. The large, chunky *kea* feeds on fruits and *grubs* (immature insects). It also eats dead animals it finds on the ground. The kea is popular with tourists because of its habit of perching on cars to beg for food. The large, forest-dwelling *kaka* has a long, strong beak that it often uses to tear apart dead wood in search of insects. The *kakapo,* or owl parrot, has an owllike face and cannot fly. Unlike most parrots, the bird is *nocturnal*—that is, it sleeps during the day and becomes active at night. The owl parrot is close to extinction because of mammal predators that people have introduced to New Zealand. These predators include rats, cats, and mongooses.

Parrots of Africa and southern Asia. Hanging parrots are tiny, mainly green parrots of southeastern Asia and the islands of Indonesia. Their name comes from their strange behavior of roosting upside down at night like bats. The *rose-ringed parakeet* lives in tropical Africa and southern Asia. It has a long tail, a bright red bill, and a bright green head. The nine species of *lovebirds* are small African parrots. They have short, rounded tails and rather large bills. They are called lovebirds because they use their bills to caress each other. The large *gray parrot,* from the west African rain forests, is a popular bird pet because it can learn to say words.

Parrots and people. People should keep parrots in clean, warm cages large enough so that the birds can exercise. Parrots need water, fresh air, and a variety of foods, including seeds, fruits, and vegetables, to stay

healthy. When well cared for, parrots can live extremely long lives. Several kinds of large parrots are known to have lived for more than 50 years in captivity. Smaller species, such as parakeets, can live up to 20 or 30 years.

Parrots are among the most intelligent birds and can learn to solve fairly complex problems. Many species of parrots are prized for their ability to repeat words or to learn complicated tricks. The gray parrot can learn new phrases within hours of teaching. It even has been shown to use human words or other symbols to communicate feelings such as hunger, fear, or boredom.

Parrots may carry the disease *psittacosis,* also called *ornithosis,* which can be transmitted to people who handle infected birds or breathe dust contaminated with their droppings. Because of this disease, all parrots must be examined by a health officer before being shipped into the United States and some other countries.

Many parrots are in danger of extinction, largely because people have destroyed much of their habitat. Some dealers sell illegally captured wild parrots at high prices. People should buy parrots only from licensed dealers who sell birds that were bred in captivity.

John W. Fitzpatrick

Scientific classification. Most scientists classify parrots in their own family, Psittacidae, in the order Psittaciformes. However, many specialists now recognize three separate families, the Loriidae (lories and lorikeets), Cacatuidae (cockatoos and cockatiels), and Psittacidae (true parrots and parakeets).

Parrotfish is the name of a group of about 75 species of fish that live around coral reefs in tropical and subtropical seas. They get their name from their unusual front teeth, which resemble a parrot's beak.

Parrotfish range in size from 4 inches (10 centimeters) to more than 4 feet (1.2 meters). They have thick bodies covered with large, thick scales. Most parrotfish are brightly colored, and most change color during their lifetime. In some species, a fish born female will later become a male.

Parrotfish feed mostly on algae, which they scrape off rocks and corals with their strong teeth. Many parrotfish feed on sea grasses around coral reefs, often grazing in large schools. The *queen parrotfish,* which lives in tropical parts of the western Atlantic, sometimes grazes in groups of three or four females and one male. Parrotfish eat during the day and rest at night. Many species of parrotfish form a thin, transparent, cocoonlike covering around themselves at night and rest in it until daylight.

Scientific classification. Parrotfish are in the family Scaridae. The scientific name for the queen parrotfish is *Scarus vetula.*

Parry, Sir William Edward (1790-1855), a British naval officer and Arctic explorer, led official expeditions in 1819, 1821, and 1824 in search of the Northwest Passage. Parry discovered Melville Island on one of these voyages (see **Melville Island**).

Sir William Edward Parry

In 1827, Parry sailed in his ship *Hecla* in an attempt to reach the North Pole by way of Spitsbergen. At Trurenberg Bay, he and his party left the ship and started north. The 28 members of the expedition took two boats and enough supplies for about 70 days. Steel runners attached to the boats enabled them to travel on the ice as well as to sail on the water. The expedition reached 82°45′ north latitude, within 500 miles (800 kilometers) of the North Pole. It was the farthest north any explorer had gone until then and remained a record until 1876.

Parry described his travels in *Voyage for the Discovery of a Northwest Passage* (1821) and *Narrative of an Attempt to Reach the North Pole in Boats* (1828). He was born in Bath, England. Barry M. Gough

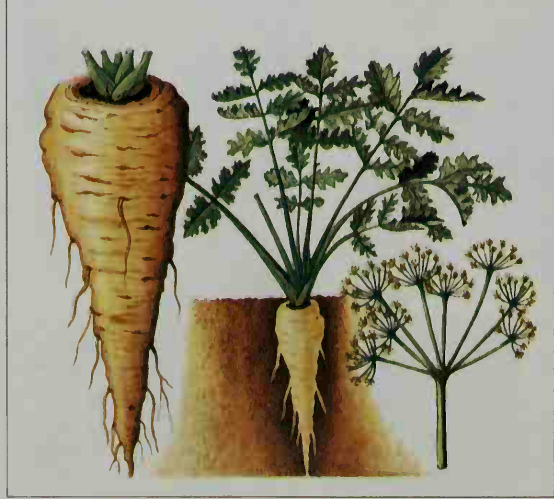
leaves. The fresh leaves are used mainly to decorate meat dishes and salads. The leaves of parsley can also be dried and used in soups.

A special kind of parsley grown in Germany, and occasionally in America, is called Hamburg parsley. This plant produces a long root that may be stored for winter use. Hamburg parsley is used as a soup flavoring.

Parsley is an excellent source of all vitamins. It is especially rich in vitamins A and C and in the minerals iron and calcium. But it is usually eaten in such small quantities that it has little effect on a person's health.

Parsley seed is sown in greenhouses, hotbeds, or open beds. It sends up leaves slowly and unevenly. The plants are moved to the garden about a week before the last spring frost. From 6 to 10 plants are enough for a family. A few leaves at a time are picked off the plant. Sometimes parsley plants are potted and grown indoors in a sunny window during winter.



Parsley was first grown in Sardinia and southern Italy. Early Romans used parsley to fashion garlands that crowned their military heroes and athletic heroes.

Albert Liptay

Scientific classification. Parsley belongs to the parsley family, Apiaceae or Umbelliferae. It is classified as *Petroselinum crispum.*

Parsnip is a biennial vegetable with many deeply and finely lobed leaves. The edible part of the parsnip is the plant's long tapering white root. Parsnips are a common plant in home gardens, but they have little commercial importance. Parsnips are related to carrots and dill.

The parsnip grows best in a deep rich soil. The seeds must be sown in early spring. The plants come up slowly and unevenly. A few radish seeds are usually mixed with the parsnip seeds. The radishes come up quickly and mark the rows of parsnips so they can be cultivated. If parsnips are neglected they can become troublesome weeds, as wild parsnips are. Parsnip roots grow slowly until the cool weather of fall. Then they grow rapidly. Parsnip roots are not injured by freezing, and are often left in the ground over winter.

Parsnips are usually free from insect enemies and suffer from few diseases. The parsnip provides moderate amounts of vitamins and minerals. Its calorie level is similar to that of the potato.

The parsnip is native to the Rhine Valley in Europe. It was known and probably used as food early in the Christian Era. It was cultivated in England in 1592 and was grown in New York by 1806. Albert Liptay

Parsons, Elsie Clews (1875-1941), was an American cultural anthropologist. She studied the cultures of Indian groups in North, Central, and South America. She also recorded folk tales of black peoples of North America and the West Indies.

In all her studies, Parsons emphasized the effect of contact between different cultures. In 1915, she traveled to the Southwestern United States, where she first studied American Indians in their natural environment. She recorded specific data on these cultures and included accounts of their customs, folklore, and rituals. Parsons wrote numerous books, including *Mitla: Town of the Souls* (1936) and *Pueblo Indian Religion* (1939).

From 1918 until her death, Parsons served as assistant editor of the *Journal of American Folklore.* In 1940, she became the first woman elected president of the American Anthropological Association.

Parsons was born in New York City. She received a Ph.D. degree in sociology from Columbia University in 1899. Nancy Oestreich Lurie

Parsons, Talcott (1902-1979), was an American sociologist. He is considered the most important theorist of the sociological school of thought called *structural-functionalism.* This school stressed the importance of social status and institutions in a society (see **Sociology** [Development of social research]).

Parsons regarded society as a system whose parts fit together and function to maintain the stability of the society. According to Parsons, every society has three parts: (1) the individual, (2) the relationships among many individuals, and (3) the society's culture in general. Any change in one part causes a reaction in and from the other parts.

Parsons was born in Colorado Springs, Colorado, and graduated from Amherst College in 1924. He later studied at the London School of Economics and Political Science and, in 1927, he received a doctorate from the University of Heidelberg in Germany. Parsons taught at Harvard University from 1927 to 1973. Parsons's books include *The Structure of Social Action* (1937) and *The Social System* (1951). Neil J. Smelser

Parthenon, *PAHR thuh nahn,* is an ancient Greek temple in Athens. The temple stands on a hill called the *Acropolis* overlooking the city. The Parthenon was dedicated to Athena, the city's patron goddess. It is probably the best example of ancient Greek architecture.

The Greeks erected the Parthenon between 447 and 432 B.C. The temple was designed by the Greek architects Ictinus and Callicrates. The Greek sculptor Phidias designed the sculptural decoration for the building. The Parthenon became a Christian church about A.D. 500. After Turkish Muslim forces captured the city, in the mid-1400's, the Parthenon served as a mosque.

The Parthenon is an ancient Greek temple in Athens that was built to honor Athena, the patron goddess of the city. It was constructed entirely of white marble.

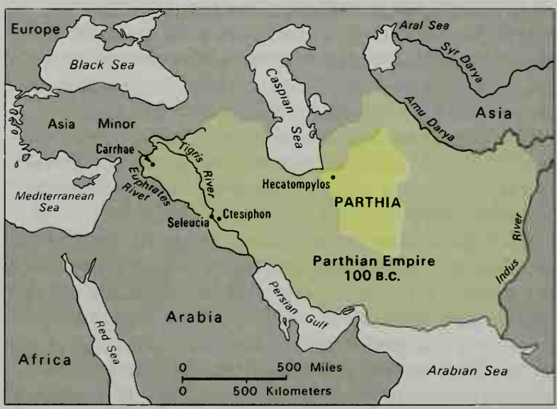
Warren Churg, Art Resource

In 1687, the Parthenon was badly damaged when the /enetians tried to conquer Athens. The Turks were us- ng it for storing gunpowder, which exploded and vrecked the central part of the building. The remaining culpture has since been moved to the Acropolis Muse- ım in Athens and the British Museum in London (see Elgin Marbles). Today, only ruins of the building remain.

The Parthenon was built entirely of *Pentelic marble,* a vhite marble that was brought from Mount Pentelicus 1 miles (18 kilometers) from Athens. The temple is a rec- angular building that measures 237 feet (72 meters) long ınd 110 feet (34 meters) wide. It stands about 60 feet (18 neters) high.

The Parthenon contains a central enclosed space, alled a *cella,* which is divided into two rooms. One of he rooms once contained a huge gold and ivory statue of Athena, and the other room once served as a treasury. A total of 46 Doric columns surround the cella (see Column [The Doric column]).

Brightly painted sculpture originally decorated the Parthenon. Sculptures once filled the two *pediments* (tri- ngular ends of the roof). The eastern pediment was lecorated with scenes showing the birth of Athena. The vestern pediment showed the battle between Athena nd the sea god Poseidon for the control of Athens.



Around the top of the outer wall above the columns of he Parthenon was a series of small sculptured panels alled *metopes.* The metopes showed famous mytholog- cal battles between the Lapiths and the centaurs, the ods and a race of giants, and Greeks and Amazons. These sculptured panels also presented battle scenes rom the Trojan War. Along the outer wall of the cella vas a continuous horizontal *frieze* (decorated band). The rieze showed the people of Athens, including Athenian fficials, priests, maidens, and young men on horseback, n the annual procession honoring the birthday of Athena. Restoration work on the Parthenon began in 1986. William J. Hennessey

Parthia, *PAHR thee uh,* was an ancient kingdom south- east of the Caspian Sea, in Asia. Parthians lived a simple life and were noted as warriors. Hecatompylos was the capital of Parthia.

The Parthians were independent until the 500's B.C., when Cyrus the Great of Persia conquered them. Alexander the Great also conquered Parthia, and it later became part of the Seleucid kingdom. By 235 B.C., Parthia had regained its independence, and it soon ruled a large empire in the East.

Parthia fought several wars against the Romans, de- feating Crassus in 53 B.C. and Mark Antony in 36 B.C. and losing to Trajan in A.D. 116. A Persian revolt overthrew the Parthian rulers about 226, and Parthia later became a part of the Sassanid Empire that was founded by Ardashir I. Thomas W. Africa

Parti Québécois, *pahr TEE kay beh KWAH,* is a politi- cal party in Quebec, the largely French-speaking prov- ince within mainly English-speaking Canada. The Parti Québécois, often called the PQ, calls for Quebec to sep- arate from Canada and become an independent nation.

The Parti Québécois was founded in 1968 with René Lévesque, a member of Quebec's legislature, as its first leader. The party gained control of the provincial legisla- ture in elections held in 1976. In 1980, the PQ conducted a referendum on whether to open discussion with the federal government of Canada concerning what was called *sovereignty association* between Quebec and Canada. Such an association would have given Quebec political independence while maintaining its economic ties to Canada. The referendum was decisively defeated.

The PQ lost control of the legislature in 1985 but regained power in 1994. In 1995, the people of Quebec voted on another referendum backed by the PQ. The referendum proposed sovereignty for Quebec but suggested the possibility of a special economic and political relationship between an independent Quebec and Canada. It was narrowly defeated. J. L. Granatstein

Participle is a verb form used as an adjective without losing its character as a verb. Like a verb, a participle may have an object or an adverbial modifier.

A word can often be identified as a participle only because it takes an object. In the sentence *The shouting mob, hurling stones, moved forward,* the word *shouting* is an adjective that modifies *mob.* The word *hurling* also modifies *mob,* but it is a participle because it has an object, *stones.*

A verb has two participles in the active voice. The present participle—for example, *drawing*—expresses action in progress. The past participle, *drawn,* expresses finished action. The perfect participle, *having drawn,* is a modified form. The participle forms in the passive voice are *being drawn* for the present tense, *drawn* for the past tense, and *having been drawn* for the perfect tense.

A present participle used as a noun is called a *gerund.* Gerunds, even though they function as nouns, keep the characteristics of a verb. In the sentence *Talking nonsense is sometimes fun,* the word *Talking* is the subject of *is,* but *nonsense* is the object of the gerund. In *By talking good sense, he won respect,* the word *talking* is the object of a preposition. Patricia A. Moody

Particle, Subatomic. See Subatomic particle.

Particle accelerator is a device that speeds up the movement of tiny bits of matter. These particles are either *ions* (electrically charged atoms) or electrically charged *subatomic particles,* objects that are smaller than an atom. The particles travel through an accelerator in a narrow beam. In accelerating the beam, the machine increases the particles' energy of motion.

Uses of accelerators. Physicists use accelerators to discover and study subatomic particles and the forces that govern them. The accelerator forces beams of subatomic particles such as positively charged protons or negatively charged electrons to strike a stationary target or to collide with another beam that is moving in the opposite direction. The resulting impacts break particles away from the target or cause other subatomic particles to form. Devices called *particle detectors* located near the points of impact provide information about particles that fly away from these points.

Other scientists use accelerators to create and study atoms of chemical elements that are heavier than uranium, the heaviest natural element. In this case, nuclei (singular, *nucleus*) in beams of ions combine with target nuclei to form heavy elements. The nucleus is the dense, core region of an atom, consisting of protons and electrically neutral neutrons.

Still other researchers accelerate beams to probe the structure of the atomic nucleus. Because some accelerator experiments break away pieces of nuclei, the machines are sometimes called *atom smashers.*

Researchers in industry and other areas use intense X rays produced by special electron accelerators. A beam of electrons sends out X rays when it passes through a *magnetic field,* a region of space in which a moving electric charge is acted on by magnetic force. One use of these rays is to produce transistors on experimental computer chips.

Physicians use particle beams to destroy tissue in cancerous tumors. Doctors also use X rays generated by accelerators to diagnose and treat cancer.

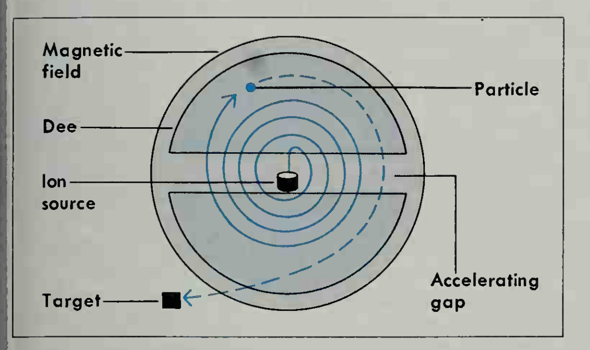
How accelerators work. Accelerators use electric force to speed up electrically charged particles. To prevent loss of energy from collisions with air molecules, the particles travel through pipes from which almost all the air has been pumped.

Physicists measure the energy of accelerated particles in *electronvolts* (eV). One electronvolt is the amount of energy gained by an electron as it moves freely through a potential difference of 1 volt. Accelerators can produce particles with energy in the range of thousands of electronvolts (keV), millions of electronvolts (MeV), billions of electronvolts (GeV), or trillions of electronvolts (TeV).

Accelerators have two basic shapes. In a *linear accelerator,* the beam travels in a straight line. In a *circular accelerator,* the particles travel in a nearly circular path. This article describes the main kinds of accelerators.

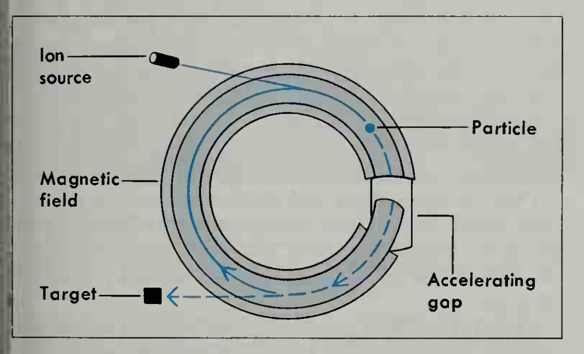
The Cockcroft-Walton accelerator, a linear machine, was the first accelerator to break up atomic nuclei. Physicists John D. Cockcroft of Britain and Ernest T. S. Walton of Ireland invented this machine in 1929. In 1932, they used it to accelerate protons to 500 keV and break up nuclei. Today's machines speed up protons, electrons, and ions. Most of them serve as beam sources for more powerful accelerators.

A Cockcroft-Walton accelerator has a long pipe with an *electrode* (electric terminal) at one end. This electrode receives a high voltage of the same kind—positive or negative—as the particles to be accelerated. At the other end is an electrode whose voltage is zero. This electrode has a hole through its center and is connected to the first electrode by a tube that carries the beam.



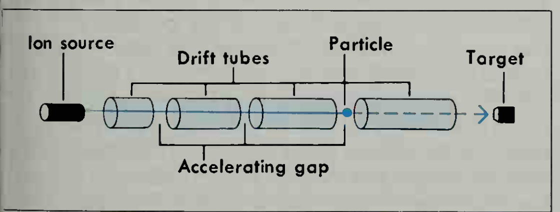
The machine releases the particles to be accelerated near the charged electrode. The voltage in this electrode repels these particles. The particles fly through the tube and pass through the hole. A Cockcroft-Walton accelerator can boost particles to about 750 keV.

The Van de Graaff generator can accelerate protons, electrons, and ions to about 15 MeV. United States physicist Robert J. Van de Graaff built his first high energy accelerator in 1931. Hundreds of such accelerators have been built, more than all other types combined.



The machine has a hollow metal sphere mounted at one end of a pipe. A belt runs over a pulley located beside a source of electric charge and a pulley next to the sphere. The source puts a charge on the belt. A metallic brush transfers the charge to the sphere. When the charge on the sphere builds to a certain strength, particles that have the same kind of charge—positive or negative—are released near the sphere's inner surface. These particles plunge to the other end of the machine, pass through a hole, and strike a target.

The tandem Van de Graaff generator has a sphere located at the center of a long pipe. The sphere receives a positive charge. This charge attracts negative ions that are inserted at one end of the pipe. When the ions reach the center, they pass through a thin target that removes two electrons from some of them. The loss of electrons makes these ions positive, so the sphere repels them to-



How particle accelerators work

In a cyclotron, a particle is drawn out from an ion source by one of the semicircular electrodes called *dees.* A magnetic field causes the particle to travel in a circular path. Each time the particle crosses an accelerating gap, it receives an energy boost and moves outward until it collides with a target.

In a synchrotron, a particle is bent by a magnetic field to move in a fixed circular orbit. As the particle gains energy, the magnetic field grows stronger to keep it moving on the same path. After crossing an accelerating gap a number of times, the particle reaches its peak energy and is guided to a target.

WORLD BOOK diagrams by Art Grebetz

In a standing-wave linear accelerator, a particle moves in a straight line through a series of drift tubes. As the particle passes through accelerating gaps between the tubes, it gains speed and builds up energy. The tubes enable the particle to maintain its speed so it will strike a target with maximum force.

ward the other end of the pipe. They gain additional energy as they fly to the end of the pipe. A tandem machine can produce ions with twice the energy of a single Van de Graaff generator.

The standing-wave linear accelerator boosts protons to energies up to 200 MeV by generating an alternating *electric field.* The field is part of an electromagnetic wave produced by vacuum tubes called *klystrons.* The wave, called a *standing wave,* extends the length of a horizontal pipe and vibrates across the pipe's width.

Along the length of the pipe, the field alternates between positive and negative. When the field is positive, it accelerates the protons in the desired direction. But when it is negative, it tends to accelerate them in the opposite direction.

The field does not actually accelerate protons the "wrong way," however, because the accelerator contains metal *drift tubes* that block the field. The tubes are installed end-to-end the length of the pipe, with gaps between them. The vibration of the wave is timed so that the protons are inside the tubes when the field would accelerate the protons the "wrong way."

The traveling-wave linear accelerator speeds up electrons. A wave generated by klystrons travels the length of a horizontal pipe. The electrons travel with the wave's negative field, gaining energy as they go—much as a surfer rides an ocean wave. The electrons move so quickly that the positive field cannot catch up with them, so the accelerator needs no drift tubes.

The longest linear accelerator in the world is a traveling-wave device at Stanford Linear Accelerator Center (SLAC) in Palo Alto, Calif. This machine, which began operating in 1966, is 2 miles (3.2 kilometers) long. In the late 1980's, SLAC added a circular structure to one end of the machine, enabling it to operate as a two-beam collider. In this case, the machine accelerates a beam of electrons and a beam of *positrons,* each with an energy of up to 50 GeV. A positron is a form of antimatter—a positively charged counterpart of an electron. In a head-on collision of a matter particle and its antimatter counterpart, all the mass in the two particles turns into energy. An instant later, most of the energy turns into new particles.

The cyclotron is the simplest circular accelerator. American physicist Ernest O. Lawrence invented the cyclotron in 1930. He received the 1939 Nobel Prize for physics for this achievement.

In a cyclotron, the particles travel in a vacuum chamber located between the poles of an electromagnet. The chamber also contains two hollow, D-shaped electrodes, mounted with their straight sides facing each other and a gap between them. The cyclotron generates an alternating electric field across the gap.

Charged particles are released at the center of the machine. The electric field accelerates them into one of the electrodes. The electromagnet generates a magnetic field that makes the particles follow a spiral path leading back to the gap. By the time they arrive, the electric field has reversed itself, so the particles are accelerated across the gap in the opposite direction. Again, the particles follow a spiral path and are accelerated across the gap. This process continues until the particles hit a target or spiral out of the cyclotron.

The energy of particles in a cyclotron is limited by the diameter of the magnet and the strength of the magnetic field. The largest cyclotron ever built could accelerate protons to 720 MeV.

The synchrotron reaches higher energies by guiding particles along a racetracklike path of alternating straight and curved sections. At each curved section, one or more electromagnets bends the beam through only a relatively small arc. The particles follow the same path over and over. At one or more of the straight sections, the particles pass through a linear accelerator that

gives them a boost. As the particles gain speed, the synchrotron automatically increases the magnetic field to hold them on course.

The world's most powerful accelerator is a synchrotron at the Fermi National Accelerator Laboratory (Fermilab) near Batavia, Illinois. This machine lies in a tunnel that measures 3 $\frac{9}{10}$ miles (6.3 kilometers) in circumference. In 1972, its first year of operation, the machine accelerated protons to 400 GeV. Since 1987, it has collided beams of protons with beams of antiprotons, antimatter counterparts of protons. Each beam can reach an energy of about 980 GeV.

In January 1993, digging began for what would have been the largest and most powerful accelerator ever built, the Superconducting Supercollider (SSC). The tunnel, near Waxahachie, Texas, would have been 54 miles (87 kilometers) in circumference. The SSC would have collided two proton beams, each with an energy up to 20 TeV. In the fall of 1993, the United States Congress canceled the SSC as a cost-cutting measure.

The world's longest accelerator tunnel is located at the CERN research center near Geneva, Switzerland. The tunnel measures 17 miles (27 kilometers) around. It housed an accelerator called the Large Electron-Positron (LEP) collider when it began operating in 1989. In 1996, CERN scientists changed its name to LEP2 to reflect a major increase in beam energy. LEP2 collided electrons and positrons at energies up to 104.5 GeV per beam.

CERN shut down LEP2 in 2000 so that construction could begin on another accelerator in the same tunnel. The new machine, the Large Hadron Collider (LHC), would collide two beams of protons at energies up to 7 TeV per beam. Also in 2000, a machine called the Relativistic Heavy Ion Collider (RHIC) began operating at Brookhaven National Laboratory on Long Island, New York. The RHIC accelerates gold ions through two tubes that are 2.4 miles (3.8 kilometers) in circumference. The machine is designed to operate at energies up to 100 GeV per proton or neutron. Robert H. Particle detector is a device that physicists use to observe *subatomic particles,* units of matter smaller than an atom. Most particle detectors are installed in large machines called *particle accelerators.* An accelerator speeds up a beam of subatomic particles to almost the speed of light. It then directs the beam into a stationary target or forces it to collide with a beam moving in the opposite direction. The resulting impacts produce other subatomic particles. Detectors near the impact points reveal details about the mass, energy, electric charge, and other properties of the particles.

Physicists have conducted experiments with particle accelerators and detectors since the early 1930's. Scientists also use particle detectors to study *cosmic rays,* subatomic particles that originate in outer space.

How particle detectors work

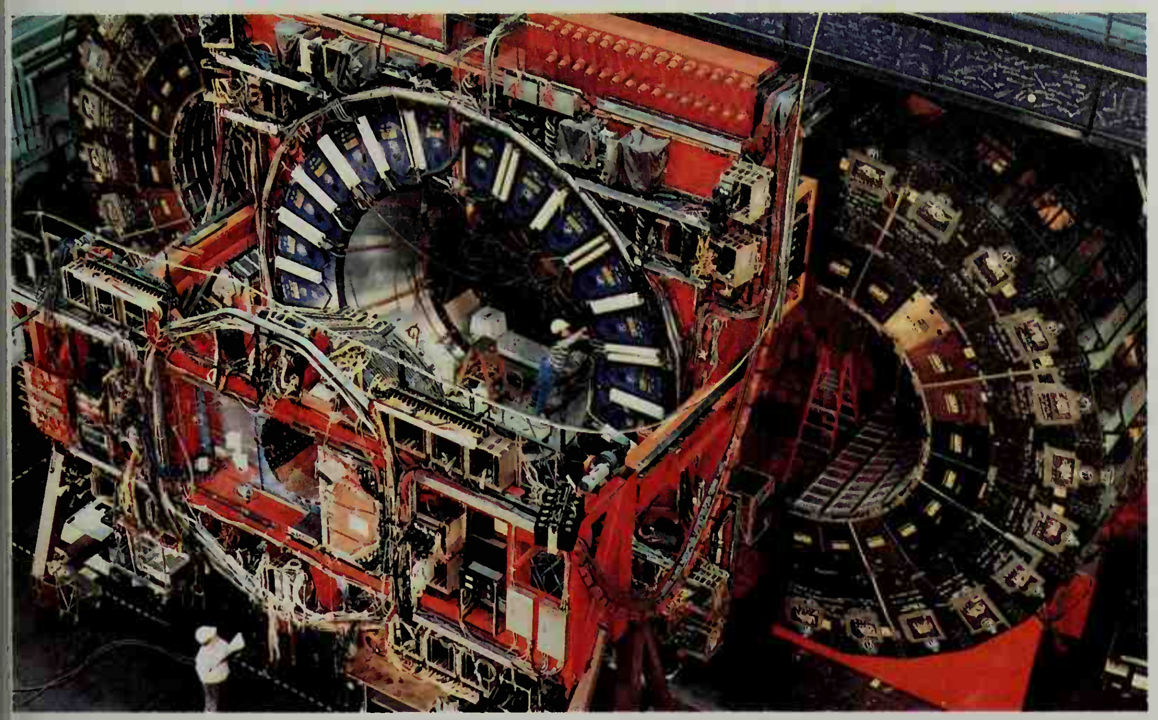
All particle detectors work by recording transfers of energy. Subatomic particles transfer this energy to atoms that are part of the particle detector.

A particle that carries an electric charge transfers small amounts of its energy electrically. As the particle moves through the detector, its charge interacts with charges in atoms of the detector. The resulting changes in the atoms trace out the path of the particle.

Certain particles cannot transfer energy electrically. The neutrino, for example, cannot do so because it carries no electric charge; and the neutron has internal electric charges that cancel one another. Such particles do, however, interact nonelectrically with atoms in the detector. These interactions produce charged particles that then transfer energy electrically. By studying these secondary particles, physicists can determine properties of the uncharged particles.

Photographic materials and devices called *cloud chambers, bubble chambers,* and *spark chambers* detected particles in early accelerators, but are not used in modern machines. Instead, today's accelerators use *tracking chambers, sampling calorimeters, scintillators,* and combined systems of detectors.

Types of particle detectors



Photographic films and plates were among the earliest particle detectors. A particle passing through a photographic material "exposed" the material. Developing the film revealed the place where the particle passed through.

Cloud chambers used an *ion trail* left by a subatomic particle passing through a gas. The particle created this trail by transferring energy to *electrons* in the gas. An electron is a negatively charged particle that orbits an atomic nucleus. When a particle transfers a certain amount of energy to an electron orbiting a nucleus, the electron leaves its orbit. An atom's negative charges are usually balanced by an equal number of positive charges. So when an electron leaves its orbit, it leaves behind a positively charged atom—that is, a positive ion.

British physicist Charles T. R. Wilson invented the cloud chamber in 1911. In his invention, which became known as the *Wilson cloud chamber,* a container held a mixture of a gas and a vapor. Vapor condensed around the ions in the ion trail to form droplets. The droplets were visible as streaks that represented the particle paths, and were photographed.

Bubble chambers caused a subatomic particle to produce a trail of small gas bubbles in a liquid. The liquid was first heated above its boiling point, but held under high pressure to prevent it from boiling. The pressure was then reduced rapidly so the liquid would boil at the slightest disturbance. Subatomic particles disturbed the liquid, causing gas bubbles to form along their paths. Donald A. Glaser, an American physicist, invented the bubble chamber in 1952. He won the 1960 Nobel Prize for physics for this invention.

Spark chambers caused an electrical discharge, somewhat like a small lightning strike, along an ion trail produced by a particle. A spark chamber was a box containing a series of thin metal plates mounted parallel to one another. The chamber was filled with neon gas or

another *noble gas* (a gas that does not normally react with other substances). The gas atoms that were ionized could conduct electric current, but the normal atoms could not.

To detect a particle, the chamber applied voltage to the plates. As a result, current in the form of sparks jumped from plate to plate along the particle path. Japanese physicists Shuji Fukui and Sigenori Miyamoto built the first practical spark chamber in 1959.

Tracking chambers trace particle paths by producing an electric signal, rather than a visible trail. Some of these detectors use an electric field to gather ions generated by subatomic particles onto a wire, a strip, or a pad. The ions produce pulses of electric charge. Electronic circuits enlarge the pulses so that they can be measured and recorded as digital data on magnetic tape. Georges Charpak, a Polish-born French physicist, received the 1992 Nobel Prize for physics for his invention of the multiwire proportional chamber, the first modern tracking chamber.

Sampling calorimeters collect ions produced by a subatomic particle as it passes through a gas or, more commonly, a liquid. The main use of a sampling calorimeter is to determine a particle's energy of motion, rather than to determine its position extremely accurately—as a tracking chamber does. This detector is based on a relationship between energy of motion and ionization: The number of ions collected for a particle that stops within the detector is approximately proportional to the particle's energy of motion.

Scintillators produce light when particles transfer energy to them. The light, in turn, strikes devices called *phototubes* or *photodiodes,* which then produce electric signals.

Scientists often build particle detectors between or around the poles of an electromagnet. The magnet causes charged particles to move along curved paths. From these curves, scientists can determine the momentum of particles.

Combined systems. Modern detectors are usually arranged in groups that work together. A combined system can measure properties of hundreds of subatomic particles at the same time. Physicists need such systems because modern accelerators commonly produce hundreds of particles in a single interaction. Generally, scientists can understand the interaction only by measuring a large number of these particles.

The number of interactions occurring in a combined system is often so large that only a small fraction of them can be recorded. The selection of interactions to record and the interpretation of the recorded data require tremendous amounts of computing.

A combined system may weigh thousands of tons and cost tens of millions of dollars to build. It may fill a large room and contain hundreds of thousands of individual wires, scintillators, and other components. It may take hundreds of physicists 10 years or more to design and build a large detector and to use it to gather and analyze data. Bruce G. Gibbard

Partnership is an association formed by two or more people to carry on a business. The people usually agree either in writing or verbally to become partners. But people who run a business together and share the profits are usually considered partners, even if they do not intend to be.

Rights and responsibilities of partners. All partners have equal rights and obligations in running the business, unless they have agreed on another arrangement. Any disagreement that arises among them is decided by majority vote. Each partner is an *agent* for the other partners. Ordinarily, therefore, anything a partner does that seems to be carrying on the business in the usual way is binding on the other partners.

All partners share in the profits of the business, but they do not necessarily share equally. The size of each share is agreed upon when the partnership is set up. It depends on how much money or property each contributes to get the business started, and on the kind and amount of work each partner is to do. Every partner is expected to devote time to the business. If one does more work than the others, the partners may agree to pay that person a salary as well as a share of the profits. Unless a system for sharing the debts of the partnership is set up formally, partners share their debts equally.

All the partners must be faithful to one another in their business dealings. No partner may enter into a transaction in the same line of business as the partnership without sharing the profits with the other partners. Neither may any partner use the funds or property of the partnership as his or her own.

All partners are liable for any debts acquired by the business. These debts are normally paid out of funds or property belonging to the business. If they cannot be paid in this way, any other property of a partner can be taken by the people to whom the debt is owed. A person can lose much money by belonging to a partnership that fails. To avoid such loss, many states allow *limited partnerships*. A *limited partner* may not take an active part in running the business, but is liable only for the amount of money he or she has invested. If a person wants to take part in running a business and still not risk losing more than he or she has invested, that person must form a corporation. See **Corporation.**

Changing or ending a partnership. No new partner may join the partnership without the consent of all the members. A new agreement must then be made, stating what the new partner must contribute and what will be his or her share of the profits. A person who wishes to leave the business can agree with the other partners on a price for buying him or her out. If the partners cannot agree, that person may have the business closed out and the property sold in order to take his or her share in cash. When a partner dies, the people who are named to handle the estate have the same rights.

Under the law, all partners are co-owners of the property belonging to the business. The Uniform Partnership Act, which is in force in most states, permits a partner to sell his or her interest in the partnership, but not in a particular piece of property. Similarly, people to whom a partner owes money may seize that partner's interest in the business, but not in any one piece of property. When a partner sells his or her interest, or when creditors seize it, the buyer or creditors can collect that partner's share of the profits, but they cannot help run the business. Robert B. Carson

Parton, Dolly (1946-), is a popular country music singer and songwriter known for her expressive songs, lilting voice, and striking stage appearance. She is also a motion-picture actress and successful businesswoman who runs her own music publishing and film production companies.

Parton has starred in a number of movies, including *Nine to Five* (1980) and *Steel Magnolias* (1989). She has composed many of her biggest hit songs, such as "Jolene," "Coat of Many Colors," "Two Doors Down," "Here You Come Again," "I Will Always Love You," and "Nine to Five." In 1986, she opened the Dollywood theme park in Pigeon Forge, Tennessee. In 2001, Parton won the Grammy award for best bluegrass album of the year for *The Grass Is Blue.*

Dolly Parton

Dolly Rebecca Parton was born in Sevier County, Tennessee. Many of her songs lovingly recall her childhood in the Great Smoky Mountains. From 1967 to 1974, she performed with country music singer Porter Wagoner in concerts and on his television series. The two recorded a series of hit duets. After Parton left Wagoner, she broadened her appeal by emphasizing more pop music material. Lydia Dixon Harden

Partridge, *PAHR trihj,* is the bird that people in the northern and western parts of the United States call *quail,* or *bobwhite.* It is known to many Southerners as

partridge. New Englanders use the term *partridge* for the *ruffed grouse.* Canadians call the *spruce grouse* the *swamp partridge* or *spruce partridge.*

However, scientists consider about 150 kinds of birds in the Eastern Hemisphere to be true partridges. The *gray partridge* is typical of this group. It has been imported into America in large numbers for breeding purposes. It is also known as the *Hungarian partridge* or *common partridge.* This bird lives throughout Europe and in northern Africa and western Asia.

The gray partridge may grow to 1 foot (30 centimeters) long. The upper body parts are ashy-gray with brown and black markings. Often there is a crescent-shaped spot of deep chestnut on the breast. The bird eats grains, tender plant shoots, and insects. It builds its nest on the ground. The female lays from 8 to 20 eggs. The gray partridge is an important game bird in the northwestern United States and the Prairie Provinces of Canada. The *chukar,* another type of partridge, is native to Asia and Europe. It also is important in the Northwest.

Donald F. Bruning

Scientific classification. Partridges belong to the subfamily Phasianinae in the family Phasianidae. The scientific name of the gray partridge is *Perdix perdix.* The chukar is *Alectoris chukar.*

Parts of speech are the word categories of languages. Words belong to the same category if they show the same formal features or if they share a common function or position in a sentence. Both *table* and *man* are nouns because they show the possessive form *(table's, man's)* and by inflection. Both *table* and *man* can also fill a position in a sentence like "The ______ is big." Nouns, verbs, adjectives, and adverbs can be defined by formal features, function, and position. Other parts of speech, such as prepositions and conjunctions, have no formal features. They can be defined by their function and position in a sentence.

Parts of speech were originally based on individual words. Often a multiword phrase or clause served the same function as a part of speech. For example, a prepositional phrase may act like an adverb. Compare "Mary slept *late* yesterday" and "Mary slept *until noon* yesterday." The parts of speech are not rigid categories. Scholars disagree as to whether the first word in noun-noun compounds such as *television set* is a noun or an adjective. Also, new words are often constructed by shifting categories. For example, shortly after microwave ovens became available, the verb *to microwave* appeared in sentences such as *John microwaved the frozen rolls.*

Scholars differ on how to describe parts of speech. The traditional description lists eight classes: nouns, pronouns, verbs, adjectives, adverbs, prepositions, conjunctions, and interjections. Some scholars prefer to distinguish *form classes*—nouns, verbs, adjectives, and adverbs—from *function words*—prepositions, determiners, auxiliaries, and conjunctions. Others distinguish *inflected classes* from all other words, called *particles.* In addition, parts of speech were originally based on classical European languages and may not be adequate for describing all of the world's languages. Pasadena, *pas uh DEE nuh,* California (pop. 133,936), is an attractive residential city. It is nationally famous as the home of the Rose Bowl, where two top college football teams play on New Year's Day or January 2. The Tournament of Roses includes a colorful parade (see **California** [picture: New Year's Day Rose Parade]). Pasadena is at the base of the San Gabriel Mountains, overlooking the San Gabriel Valley. It is about 10 miles (16 kilometers) north of Los Angeles (see **California** [political map]).

The California Institute of Technology is in Pasadena. This college manages the Jet Propulsion Laboratory for the National Aeronautics and Space Administration (see **Jet Propulsion Laboratory**). The city's manufactured products include biomedical instruments. Pasadena is the home of Fuller Theological Seminary and Pacific Oaks College. The city's cultural facilities include the Norton Simon Museum of Art, the Pacific-Asia Museum, and the Pasadena Playhouse State Theatre of California. Mount Wilson Observatory is nearby.

The site of Pasadena was once part of the San Gabriel Mission, established by Spanish priests in 1771. In 1873, the land was purchased by the California Colony of Indiana, an organization founded by Thomas B. Elliott of Indianapolis. The original name, "Indiana Colony," was changed in 1875 to *Pasadena,* an Indian word meaning *valley between the hills.* Pasadena was incorporated in 1886 and chartered as a city in 1901. It has a council-manager government. Kenneth Reich

Pascal, *pas KAL* or *PAS kuhl,* a unit in the metric system, is used to measure pressure (force per unit of area). Its symbol is *Pa.* One pascal is the pressure of a force of 1 newton acting on an area of 1 square meter (see **Newton**). If a force of 30 newtons acts on an area of 5 square meters, the amount of pressure exerted is 6 pascals. Other metric units of pressure are the *kilopascal,* which equals 1,000 pascals, and the *bar,* which equals 100,000 pascals. In the inch-pound system, pressure is measured in pounds per square inch. One pascal equals about 0.000145 pound per square inch. The pascal was named for the French scientist Blaise Pascal. Hugh D. Young

Pascal, *pas KAL* or *PAS kuhl,* **Blaise,** *blehz* (1623-1662), was a French physicist, mathematician, and philosopher. He became known for his experiments with fluids in physics and for his work on probability theory in mathematics. In a work called *Provincial Letters,* Pascal helped create a modern French prose style.

Pascal's important work on the pressure of fluids produced the principle called *Pascal's law.* This principle, developed in the 1650's, states that fluid in vessels transmits pressure equally in all directions. It explains the operation of air compressors, vacuum pumps, and hydraulic elevators, jacks, and presses (see **Pascal's law**). Pascal's experiments helped prove that air has weight and that air pressure can produce a vacuum. At the time, many scientists doubted that a vacuum could exist.

In 1654, Pascal and French mathematician Pierre de Fermat corresponded about the outcomes of games of chance. Their correspondence laid the foundation for a theory of probability. That same year, Pascal published a work on conic sections and described a triangular arrangement of numbers in which each number in any row is the sum of the two numbers immediately above it. This arrangement, called *Pascal's triangle,* can be used to calculate probabilities. Pascal also invented a calculat-

ing machine that performed addition and subtraction.

Pascal was born on June 19, 1623, in Clermont-Ferrand. He showed early brilliance as a mathematician. Pascal became absorbed in a religious movement called Jansenism and in late 1654 entered a Jansenist convent at Port-Royal (see **Jansen, Cornelius**). The Jesuit religious order charged the Jansenists with heresy and condemned Jansenist leader Antoine Arnauld. In reply, Pascal published 18 immensely popular satirical pamphlets called the *Provincial Letters* in 1656 and 1657.

From 1658 until his death, Pascal worked on a defense of Christian faith. Fragments of this uncompleted work were discovered after his death and published as *Pensées*. This work expresses Pascal's belief that there are limits to the truths reason can know, and that faith from the heart in Christian revelation is the primary guide to truths. Ronald S. Calinger

Pascal's law, *pas KALZ* or *PAS kulz,* also called *Pascal's principle,* describes the effect of applying pressure on a fluid in a closed container. It states that pressure applied to an enclosed fluid is transmitted with equal force throughout the container. The law explains why a thin-walled bottle filled with water and fitted with a cork may break when the cork is pushed down. Pascal's law was named for Blaise Pascal, a French scientist and mathematician of the 1600's. See also **Hydraulics; Pascal, Blaise.** Richard A. Martin

Paschal II, *PAS kuhl* (?-1118), was elected pope in 1099. Much of his troubled reign was occupied with the *investiture controversy.* The controversy was a quarrel over whether secular powers or the clergy had the right to *invest* (appoint) the clergy to religious offices.

In 1105, Paschal decided to support Henry V in Germany in a revolt against his father, Henry IV. In 1111, after his father's death, Henry V promised to support Paschal's plan for settling the investiture issue and, in return, the pope agreed to crown Henry as emperor. In Paschal's plan, the clergy would give up their secular powers and influence in the hope that secular leaders would leave investiture to church officials.

Paschal's plan collapsed in a storm of protest from the German clergy and nobility. Henry then kidnapped the pope and forced him to carry out the coronation. Henry also forced an agreement on investiture favorable to the imperial position. A few years later, Paschal renounced the agreement. Paschal was born in Italy. His given name was Rainerus. Thomas F. Pashtuns, *pash TOONZ,* are one of the largest ethnic groups in Afghanistan and Pakistan. They make up about half the population of Afghanistan and about one-fifth of the people of Pakistan. Most Pashtuns live near the border between Afghanistan and Pakistan.

Other names for the Pashtuns include *Pathans, Pakhtuns, Pukhtuns,* and *Pushtuns.* They speak Pashto, also called Pushtu or Pukhtu, a language related to Persian. Almost all Pashtuns are Muslims.

The Pashtuns consist of about 40 tribes divided into groups of related families. Democratic councils called *jirgah* govern tribal affairs. Although the tribes unite to fight invaders, they often feud with one another. Some of the feuds have raged for centuries.

Many Pashtuns work as farmers, raising wheat and other grains, fruits, nuts, and sugar cane. Others are nomads who breed horses and herd sheep, goats, cattle, and camels. Many farmers live in homes made of mud-brick. Most nomads live in tents made of goat hair. Some Pashtuns combine farming with nomadic herding.

Ancestors of the Pashtuns lived in what is now Afghanistan by about 4000 B.C. In the A.D. 1500's, some Pashtuns moved to present-day Pakistan. In the 1800's and early 1900's, Pashtun warriors became the dominant group among Afghans who fought and won a series of wars against the British. The United Kingdom was seeking control of Afghanistan's foreign policy as part of its competition with Russia for influence in the region.

In late 1979 and early 1980, the Soviet Union invaded Afghanistan. Pashtuns formed guerrilla bands to help repel the invasion. The Soviets withdrew from Afghanistan in 1988 and 1989. By the late 1990's, a Pashtun-dominated group known as the Taliban had taken control of most of Afghanistan. Afghan rebels, aided by the United States and its allies, forced the Taliban from power in 2001. Thomas E. Gouttierre

Pasqueflower, *PASK FLOW uhr,* is the name of three small plants with large flowers that open early in the spring. The name *pasqueflower* means *Easter flower.* Two species grow in Europe and one in North America. The North American species, called *pasqueflower* or *wild crocus,* is the state flower of South Dakota and the provincial flower of Manitoba. It grows throughout the Midwestern plains of North America. Its flowers range in color from lavender to deep purple and have yellow centers. The blossoms form on very short stems that grow longer as the seeds ripen. The fuzzy leaves have many leaflets that spread out like the fingers of a hand. Passamaquoddy Bay, *PAS uh muh KWAHD ee,* is a part of the Bay of Fundy between Maine and New Brunswick, Canada. It cuts inland for about 15 miles (24 kilometers), and averages about 10 miles (16 kilometers) in width (see **Maine** [physical map]). The tides on the rocky Maine coast of Passamaquoddy sometimes rise as much as 27 feet (8 meters). The chief towns in Maine on Passamaquoddy Bay are Eastport and Lubec. The chief towns in New Brunswick are St. Andrews, St. George, and Blacks Harbour, which is the site of the world's largest sardine factory. Campobello and Deer islands lie in the bay, and Grand Manan Island is near the entrance to the bay. Important fisheries along the bay include herring, pollock, sardine, and lobster. T. W. Acheson

Passenger pigeon is an extinct bird that was once abundant in eastern North America. The last known passenger pigeon died in 1914 at the Cincinnati Zoological Gardens. Its body is now displayed at the National Museum of Natural History in Washington, D.C.

The male passenger pigeon grew about 16 $\frac{1}{2}$ inches (42 centimeters) long, with a long pointed tail; a short, black bill; and red eyes and feet. It had a gray-blue head and body. The feathers on the male's neck and throat

were wine-colored, with green and purple highlights. The female was similar but smaller with duller colors.

Scientists estimate that as many as 3 to 5 billion passenger pigeons lived across eastern North America in the year 1500. They nested from the Atlantic Coast as far west as Montana. The birds got the name *passenger pigeon* because they traveled often to new places to look for food. They flew rapidly, sometimes in huge flocks. One flock in 1810 was calculated to have over 2 million birds, enough to block out the sun.

Passenger pigeons nested chiefly in forests of oak and beech, where they ate acorns, beechnuts, berries, and grains. Their enormous breeding colonies averaged 30 square miles (78 square kilometers) in area. Females laid only one egg on each nesting attempt.

The great number of passenger pigeons began to decline in the 1850's. Many beech and oak forests were cut for use as fuel and lumber and to clear land for farms. As a result, much of the passenger pigeon's habitat was destroyed. Hunters also killed millions of nesting passenger pigeons for food, and some even dynamited the bird's colonies. People shipped barrels full of birds to the cities. These factors, combined with the pigeon's low reproductive rate and inability to nest in small colonies, doomed the bird to extinction. Edward H. Burtt, Jr.

Scientific classification. The passenger pigeon belongs to the pigeon family, Columbidae. It is *Ectopistes migratorius.*

Passion-flower is a type of woody vine that has unusual blossoms. Roman Catholic priests of the late 1500's named it for the *Passion* (suffering and death) of Jesus Christ. They believed several parts of the flower, including the petals, rays, and sepals, symbolized features of the Passion. The flower's five petals and five petallike sepals represented the 10 apostles who remained faithful to Jesus throughout the Passion. The circle of hairlike rays above the petals suggested the crown of thorns Jesus wore on the day of his death. Passion-flowers are also called *granadillas* or *maypops.*

The priests who named the vine found it growing in what is now Latin America. Today, gardeners in many parts of the world raise passion-flowers for the blossoms. The flowers may be almost any color or combination of colors. Their diameter ranges from $\frac{1}{2}$ inch to 6 inches (13 to 150 millimeters).

Many species of passion-flowers bear a fruit called *passion fruit.* These round or oblong fruits range from yellow to purple in color and contain many edible seeds. Passion fruits taste slightly sour or very sweet, depending on the species. They are eaten whole and also are used to make juice, marmalade, ice cream, and other refreshments.

Most of the approximately 400 species of passion-flowers grow in warm regions of the world. The yellow fruit of the *purple granadilla* is the passion fruit most commonly used to make juice. Jaime E. Lazarte

Scientific classification. Passion-flowers belong to the passion-flower family, Passifloraceae, and they make up the genus *Passiflora.* The scientific name for the purple granadilla is *Passiflora edulis flavicarpa.*

Hugh Spencer, NAS

The passion-flower reminded early Roman Catholic missionaries in America of Christ's Passion, and they gave it this name.

Passion music is a vocal composition that dramatically tells the Gospel story of the suffering and Crucifixion of Jesus Christ. Passion music may involve a large chorus with instrumental accompaniment or just a few singers representing characters from the Gospels. Passion music is generally performed during Holy Week—that is, from Palm Sunday to Easter Sunday.

The oldest surviving Passion manuscripts date from the A.D. 800's, though Passion music may have existed earlier. Passions probably originated from the church custom of reciting the Gospel stories of Jesus's last days. During the 1600's and 1700's, the Passion developed into an elaborate dramatic musical form similar to the oratorio. One of the most famous works of this type is *The Passion According to St. Matthew* (1729) by the German composer Johann Sebastian Bach. It includes *recitatives* (speechlike sections), *arias* (songlike solos), choruses, and orchestral passages. Katherine K. Preston

Passion play is a dramatic performance that presents the death and resurrection of a god. The ancient Egyptians performed passion plays devoted to the god Osiris. The ancient Greeks presented similar plays dedicated to the god Dionysus. But the term *Passion Play*

Black Hills Passion Play

A passion play dramatizes the death and resurrection of a god. The Black Hills Passion Play performed in Spearfish, South Dakota, depicts the Crucifixion and Resurrection of Jesus Christ.

most often refers to plays that depict the suffering, Crucifixion, and Resurrection of Jesus Christ.

European townspeople and villagers of the late Middle Ages often staged Passion Plays. The plays enabled them to participate personally in the drama of Jesus's last days on earth.

Several towns in southern Germany, western Austria, and Switzerland continue the Passion Play tradition today. The most famous European Passion Play is presented by the town of Oberammergau in southern Germany. This play originated in 1634 as a show of thanks to God for sparing the town from a plague. The Oberammergau Passion Play normally is performed every 10 years. It lasts about 5 $\frac{1}{2}$ hours and includes over 800 performers (see **Oberammergau** [picture]). In the United States, Passion Plays are performed annually in several cities.

Passover, also called *Pesah,* is a Jewish festival that celebrates the flight of the Israelites from Egyptian slavery, probably in the 1200's B.C. The story of Passover is told in the Bible in Chapter 12 of the Book of Exodus. Passover begins in March or April, on the 15th day of the Hebrew month of Nisan. Most Jews celebrate Passover for eight days, but Jews in Israel, and Reform Jews in other countries, celebrate it for seven days.

Jews celebrate Passover in their homes at a ceremonial feast called the Seder. At the Seder, the story of the flight of the Israelites is read from a book called the Haggadah. Foods symbolizing the flight from Egypt are placed on the table. The most important symbol is *unleavened* (unraised) bread called *matzo* (also spelled *matzah*). According to the Bible, when the Israelites fled, they did not have time to let their bread rise. They made flat, unleavened bread instead. Therefore, Jews eat matzahs instead of leavened bread during Passover.

The word *Passover* comes from the Biblical story of the 10th plague, which God brought on Egypt for keeping the Israelites in bondage. The story says God killed the first-born child in every Egyptian home but passed over the homes of the Israelites. The word *Passover* also refers to the passing over of the Israelites from slavery to freedom. Lawrence H. Schiffman

Passport is a travel document that identifies the holder as a citizen of the country by which it is issued. A passport also requests other countries to give the holder safe passage and all lawful aid and protection. Sometimes a passport must have a *visa* (official endorsement) from the country a person desires to visit before entry into that country is permitted (see **Visa**).

The Department of State in Washington, D.C., issues passports in the United States. State Department officials in the following cities may also issue passports: Boston, Chicago, Detroit, Honolulu, Houston, Los Angeles, Miami, New Orleans, New York City, Philadelphia, San Francisco, Seattle, and Stamford, Connecticut. Applications may also be made before a clerk of a federal or state court authorized by law to naturalize aliens. Many U.S. diplomatic and consular offices can issue passports to U.S. citizens overseas. In Canada, passports are issued by the Department of External Affairs at Ottawa.

Many countries do not require citizens of certain other countries to have passports. United States citizens do not need passports to enter Bermuda, Canada, Mexico, and most of the West Indies. Robert J. Pranger

Pasta, *PAHS tuh,* is a food made chiefly from wheat products and water. It comes in more than 100 shapes and sizes. Some of the best known are macaroni, which consists of hollow tubes; spaghetti, which is made into long cords; and noodles, which are flat strips. Elbow macaroni has the shape of short, curved tubes, and shel macaroni resembles sea shells. Vermicelli is extremely thin spaghetti, and wide noodles are called lasagna noodles. Ravioli, another pasta product, consists of small, hollow squares stuffed with cheese or ground meat.

The word *pasta* is an Italian term meaning *dough.* The best pastas are made with medium-sized particles milled from *durum* (hard-grain) wheat. Manufacturers mix the particles with water and other ingredients, such as flour, to form a firm dough. The dough is either pressed through a machine or rolled out and cut into the proper shapes. The pasta is then dried with forced air until it is hard and brittle.

Pasta products are rich in *carbohydrates* (starches) and are a fairly good source of protein. *Enriched pasta* contains iron and the B vitamins thiamine, riboflavin, and niacin. Some pastas include such ingredients as milk or seasonings in addition to wheat products and water. Manufacturers add eggs to the pasta mixture to make egg noodles. *Green pasta* is made by mixing spinach with pasta dough.

Pasta dishes have been a specialty of Italian cooking since the 1200's, but they are now popular throughout the world. The bland flavor of pasta makes it a suitable ingredient to mix with cheese, meat, tomato sauce, and other foods. Pasta is boiled until it is soft but slightly chewy. It can then be combined with other foods in casseroles or salads. Margaret McWilliams

Pasternak, Boris (1890-1960), was a Russian poet an fiction writer. In the West, he is best known for his nov *Dr. Zhivago* (1957). Pasternak was awarded the Nobel Prize for literature in 1958. He accepted the award but then rejected it under pressure from the Soviet govern ment.

Authorities banned *Dr. Zhivago* in the Soviet Union. The novel was first published in Italy and then was trar lated into English and many other languages. Zhivago, Russian physician, experiences the suffering and disor der of his country's revolutionary period. He cannot ac cept Communist rule and tries to find happiness in lov and in the beauty of nature. The novel contains much a tobiographical material. Zhivago is also a poet and his beautiful poems are part of the book.

Boris Leonidovich Pasternak was born in Moscow. H showed great promise in musical composition and ph losophy before turning to poetry. His third book of poems, *My Sister Life* (1922), established his reputation as major Russian poet. For Russians, his greatness as a poet is paramount.

Pasternak's poems supported the Russian revolutions of 1905 and 1917, but he did not accept many of the strict doctrines of the Communist Party. During the 1930's and 1940's, the Soviet government prohibited the publication of most of Pasternak's writing. He earned a living by translating poems and plays by foreign writers, including Johann von Goethe and William Shakespeare. In 1957, the Soviet Writers Union expelled Pasternak, which meant that his works could not be published in the Soviet Union. The union reinstated him in 1987, almost 27 years after his death. In 1988, *Dr. Zhivago* was first published in the Soviet Union. Anna Lisa Crone

Pasteur, *pas TUR,* **Louis** (1822-1895), of France, made major contributions to chemistry, medicine, and industry that have greatly benefited humanity. His discovery that diseases are spread by bacteria saved countless lives. Pasteur was a great theoretical scientist who applied his basic discoveries to important practical problems in both industry and medicine.

His work in chemistry brought him his first recognition. By the age of 26, Pasteur was famous for his work on the structure of crystals. But Pasteur soon started probing the mysteries of *bacteriology* (the study of bacteria). Others saw bacteria before Pasteur did. But he was the first to show that living things come only from living things. Before that, many scientists believed in *spontaneous generation,* a theory that life could come from things that are not alive, such as dirt. Pasteur also showed that although bacteria live almost everywhere, their spread can be controlled. See **Bacteria; Spontaneous generation.**

His work in industry. Pasteur is credited with saving the silk industry and wine industry in France. In the early 1860's, he noted that wine turns bitter because of *microbes* (germs) that enter the wine while it is being made. He showed that microbes can be killed by applying controlled heat. This use of heat as a means to kill germs became known as *pasteurization.* Pasteur also used this method to preserve milk and beer, and to preserve food. See **Pasteurization.**

In 1865, Pasteur set out to help the silk industry. A disease called *pebrine* was killing great numbers of silkworms. He proved that a microbe that attacks silkworm eggs causes the disease. He showed that eliminating this germ in silkworm nurseries could wipe out the disease.

His work in medicine. Pasteur proved that many diseases are caused by germs that multiply in the body. He also proved that if microbes are weakened in a laboratory and then placed in an animal's body, the animal develops an *immunity* (resistance) to the microbe. He called this method of fighting off microbes *vaccination.* Pasteur proved the value of vaccination by vaccinating sheep against a disease called anthrax (see **Anthrax**). He also showed that vaccination could be used to prevent chicken cholera and other animal diseases.

Pasteur began in 1881 to study rabies, a deadly disease spread by the bite of rabies-infected animals. He spent endless hours in his laboratory seeking a vaccine to prevent rabies. One day in 1885, a rabid dog bit a boy named Joseph Meister. The boy's parents begged Pasteur to save their son. Pasteur hesitated to use his new vaccine on a human being, but he finally agreed. After several weeks of treatment, the vaccine proved successful. The boy did not get rabies. See **Rabies.**

His life. Pasteur was born on Dec. 27, 1822, in Dôle, France. His family moved to Arbois, where he received his early education. Pasteur was a slow but careful student who showed a talent for art. He later studied chemistry at the École Normale Supérieure in Paris.

In 1849, Pasteur became a chemistry professor in Strasbourg, France, where he began studying *fermentation,* a type of chemical breakdown of substances by microbes (see **Fermentation**). His work brought such improvements in brewing and winemaking that some say France was able to save enough money to pay its Franco-Prussian War debt.

Pasteur became director of scientific studies at the École Normale in 1857, but he left this post in 1867 to focus on his research. In 1868, a brain stroke partially paralyzed Pasteur. Despite his poor health, he continued his work. The Pasteur Institute in Paris, a world center for the study, prevention, and treatment of disease, was founded in 1888 in gratitude to him. He served as director of the institute until his death in 1895. Pasteur is buried in a tomb in the building. Kenneth R. Manning

Pasteurization is a method of preserving food. It is most commonly used for milk, but it may also be used for beer, eggs, juice, and other food products. Pasteurization kills yeasts, molds, and *pathogenic* (disease causing) and most other bacteria. It also renders inactive certain enzymes (molecules that speed up reactions) that are naturally present in foods. It involves heating food at specific temperatures and for certain periods of time.

Almost all packaged milk sold in the world is pasteurized. Pasteurization is named after Louis Pasteur, a French scientist. In the mid-1800's, Pasteur discovered that gently heating wine would destroy most of the bacteria in it without altering the wine's flavor.

Pastorius, *pas TOH rih uhs,* **Francis Daniel** (1651-1719?), a German lawyer and scholar, founded Germantown, now part of Philadelphia. Pastorius became interested in the Society of Friends, or Quakers, at about the

time that William Penn founded the colony of Pennsylvania. Pastorius bought 15,000 acres (6,070 hectares) of land from Penn in 1683, and laid out the settlement of Germantown for German Quakers and Mennonites. Pastorius was born in Sommerhausen, Germany, near Würzburg. Oliver A. Rink

Pastry is a food baked from a stiff, short dough that is composed basically of flour, salt, shortening, and water. This dough is baked into plain, flaky, or puff pastries.

Different countries are noted for special kinds of pastry. French pastry is made from a puffy dough like that used for éclairs and cream puffs, or from a cake mixture cut into small shapes and decorated with frostings, glazed fruits, jellies, or nuts. Danish people make pastries of flaky yeast dough into which generous amounts of butter have been folded. The pastries may be filled with cream cheese, fruit, or nuts. Pie is the best-known pastry that is typically American. The flaky crust is created by folding layers of shortening between the flour and water. Kay Franzen Jamieson

Patagonia, *PAT uh GOH nee uh,* is a region in the southern part of South America. A large part of the region is desert. Indians lived in Patagonia long before white people arrived. The name *Patagonia* comes from a Spanish word that means *big feet.* The Indians were tall and wore large boots stuffed with grass.

In 1520, the Portuguese navigator Ferdinand Magellan became the first European to reach the region. In 1865, Welsh settlers came into Patagonia. The area was divided between Chile and Argentina in 1907 under the terms of an 1881 treaty.

Today, the term *Patagonia* usually refers to the Argentine section of the region. It includes the southern Argentine provinces of Río Negro, Chubut, and Santa Cruz, and the territory of Tierra del Fuego. Farmers raise sheep on large tracts of land in the region. Patagonia is an important source of energy for Argentina. Hydroelectric projects on the Limay River in northern Patagonia provide electricity. Oil fields in Patagonia yield much of Argentina's petroleum. The region also has coal and iron ore deposits. Jerry R. Williams

Patchouli, *PACH u lee* or *puh CHOO lee,* is a strongly fragrant oil used in making perfumes. The oil comes from leaves of the patchouli plant, a member of the mint family. The leaves are dried in the sun. To increase the yield of oil, leaves are sometimes allowed to undergo *fermentation* (a chemical change that breaks down certain materials). Steam is then passed through the leaves to remove the oil. Farmers grow patchouli plants in China, India, Indonesia, the Philippines, and Singapore.

Patella. See Knee.

Patent is a document issued by a national government granting an inventor exclusive rights to an invention for a limited time. A patent gives an inventor, or any other owner of the patent, the right to prevent others from making, selling, importing, or using the invention in the country that granted the patent. In the United States, patents are administered by the United States Patent and Trademark Office.

To be eligible for a patent, an invention must be new, useful, original, and not easily discovered or created. United States patent laws consider inventions to include machines, methods, manufactured products, and compositions, plus new uses of inventions in each of these categories. Patents for these inventions and new uses are called *utility patents.* Utility patents may also be obtained for improvements of inventions and for most new varieties of plant life. Utility patents have also been granted for life forms created in a laboratory by genetic engineering. These life forms have included some types of corn and mice, and many kinds of microorganisms. Another type of patent, called a *plant patent,* is available for nonpollinating plants. A third kind of patent, known as a *design patent,* covers only an article's appearance.

An invention that would be obvious to anyone of ordinary skill in a given field cannot be patented. Such an invention might involve merely a substitution of materials, a change in the size of a machine, or a combination of known concepts without new and unexpected results.

How patents protect inventors

Patents give their owners a legal monopoly of an invention. In the United States, the monopoly granted by utility patents and plant patents gives the inventor a legal monopoly of an invention. This monopoly begins on the date the patent is issued and expires 20 years after the patent application was filed. The monopoly can be extended for up to 5 years if certain delays occur in the Patent and Trademark Office, in the courts, or in the U.S. Food and Drug Administration. Design patents are issued for 14 years. A patent can be renewed only by a special act of Congress.

Anyone who applies for a patent must pay a filing fee and, if the application is allowed, an issue fee. Utility patent holders who wish to keep their patents in force for the full 20-year period must make additional payments $3\frac{1}{2}$, $7\frac{1}{2}$, and $11\frac{1}{2}$ years after their patents were issued.

On average, the Patent and Trademark Office takes more than a year to process a patent application. To avoid delay in getting a newly invented product on the market, most manufacturers start to produce it soon after filing for a patent. The manufacturer marks the product "Patent Pending" or "Patent Applied For." This warning has no legal value, but it discourages imitation. A patented invention may be marked "Patented," together with the patent number. Copying a patented invention without permission is called *infringement.* The patent owner may sue for damages and a court order requiring the infringer to stop copying the invention.

An inventor may sell all or part of the rights given by a patent. The inventor may also license these rights to a manufacturer. Licensing gives the inventor a fee or *royalties* (payments based on sales), or both.

How to get a U.S. patent

Most governments grant a patent to the inventor who first applied for it. But in the United States, it is granted to the applicant who was the first inventor. For initial protection, an inventor should record the date the invention took shape in the mind and draw a sketch with a description of the idea. This document should be dated and signed by the inventor and two witnesses. It should be kept in a safe place.

By filing a *provisional patent application,* an inventor can establish a date of invention before building and

testing the invention. Unlike regular patent applications, provisional applications need not include *claims.* Claims define the scope of the invention and may take much time to prepare. The inventor obtains the benefit of the provisional application filing date only if he or she files a regular application within a year.

The preparation of a regular patent application that will fully protect the invention requires specialized legal knowledge. Most inventors use the services of a patent attorney or a patent agent who is registered to practice before the Patent and Trademark Office.

Before filing an application, the inventor or the inventor's attorney usually has a *search* conducted. The search involves a study of government patent files to determine whether a patent or other publication already describes the invention. United States law permits inventors to wait up to one year from the date of the publication, offer of sale, or sale of their inventions to apply for a patent.

A patent application consists of a *specification* (description), one or more drawings of the invention, and one or more claims. After the Patent and Trademark Office receives an application, an examiner conducts an official search of the patent files to learn whether the invention has already been patented or otherwise published. The application is then accepted or partially or completely rejected. If it is accepted, the inventor receives a *notice of allowance.* After payment of the issue fee, the specification and claims are printed, and the inventor receives a patent.

If the application is rejected, the inventor may amend the claims and argue for the patentability of the invention. If again rejected, an appeal may be made to the Patent and Trademark Office's Board of Patent Appeals and Interferences. If this fails, the decision can be challenged in court.

Patent laws of other countries

Patent laws vary from country to country. Most of the patent laws follow the principle that a patent is a bargain between the inventor and society. Inventors reveal their secrets in exchange for a monopoly for a limited amount of time. Society receives the benefit of the inventors' sharing their secrets. But the laws of various countries differ regarding the conditions under which applicants may make public their inventions before receiving a patent.

International patent agreements

A patent treaty now recognized by almost 100 nations, including Canada and the United States, went into effect in 1884. Each nation agrees to give citizens of the other countries the same rights to obtain a patent as it gives its own citizens. The treaty also benefits people who apply for a patent in their own country and then apply in any of the other countries within a year. Their later applications are treated as having been made on the same date as the one made in their own country.

In 1978, the Patent Cooperation Treaty (PCT) took effect. It provides for a search and a standard application form. Under this treaty, each nation retains its own patent laws, but the standard application replaces an individual nation's application. Each country then largely relies on the PCT search. Pater, *PAY tuhr,* **Walter Horatio** (1839-1894), an English essayist and critic, influenced the artistic taste of many English people in the late 1800's. Pater's most important and best-known work is the philosophic novel *Marius the Epicurean* (1885). It tells of a man in ancient Rome who admires beauty for its own sake. The novel was important in establishing the doctrines of *aestheticism,* the belief that beauty is the most meaningful thing in life. It also expressed the idea that an artist's sole responsibility is to strive for beauty. Pater's other notable work is a collection of essays on Renaissance artists, *Studies in the History of the Renaissance* (1873).

Pater was born on Aug. 4, 1839, in London. He graduated from Oxford University. Pater was elected a *fellow* (resident teacher) of Brasenose College at Oxford in 1864. The college was the center of his activities for the rest of his life. He began his career as a critic on art for two famous English magazines—the *Fortnightly Review* and *The Westminster Review.* K. K. Collins

Paterson, *PAT uhr suhn* (pop. 149,222), was one of the earliest industrial communities in the United States. It lies in northeastern New Jersey, on the Passaic River. For location, see **New Jersey** (political map). Paterson is the largest city in the Bergen-Passaic metropolitan area, which has a population of 1,373,167.

Paterson was founded in 1791. It grew from a small village near a massive waterfall on the Passaic River. Alexander Hamilton, the first U.S. Secretary of the Treasury, recognized the potential of the waterfall to provide power for manufacturing companies. He helped found the Society for Establishing Useful Manufactures (S.U.M.) to develop Paterson.

During the 1800's, Paterson became a center for textile production, a site for the construction of some of the nation's first steam locomotives, and a famous silk manufacturing center. For a brief time, the handgun developer Samuel Colt manufactured revolvers in Paterson.

In the early 1900's, Paterson was the site of a silk workers' strike and other labor disputes. The silk industry collapsed after the introduction of synthetic fibers. Many of Paterson's textile mills closed as firms moved out of state. During the 1930's and 1940's, the city was an important manufacturer of aircraft engines.

Today, service industries are central to Paterson's economy. But the city also manufactures cotton fabrics, fabricated metal products, printing machinery, and soap and other household cleaners. Many mills and other industrial sites are preserved in a historic district. Paterson has a mayor-council government. Paul G. E. Clemens

Paterson, *PAT uhr suhn,* **Katherine** (1932-), is an American author of children's books. She won the 1978 Newbery Medal for *Bridge to Terabithia* (1977). This novel tells about a friendship between a boy and girl from different cultural backgrounds and the imaginary kingdom they create. Paterson won the 1981 Newbery

Medal for *Jacob Have I Loved* (1980), a story about the rivalry between twin sisters. Paterson's other novels include *The Master Puppeteer* (1976), *Come Sing, Jimmy Jo* (1985), *Park's Quest* (1988), *Lyddie* (1991), and *Jip: His Story* (1996), which won the 1997 Scott O'Dell award. These works deal with moral issues and family life. Many of the main characters in these novels are young artists or strong thinkers.

Paterson was born in China, where her father was a missionary. She served as a missionary in Japan from 1957 to 1962. She received the 1988 Regina Medal for her contributions to children's literature.

Paterson, *PAT uhr suhn,* **William** (1745-1806), a lawyer and judge from New Jersey, was a signer of the Constitution of the United States. He helped write and presented the New Jersey Plan at the Constitutional Convention of 1787. This proposal gave each state an equal number of representatives in the national legislature. Although the plan was rejected, a compromise was later passed that gave states equal seats in the Senate. Paterson later helped win *ratification* (approval) of the Constitution by New Jersey.

Paterson was born in County Antrim, Ireland (now Northern Ireland). His family came to America when he was almost 2 years old, and William grew up in Princeton, New Jersey. Paterson graduated from the College of New Jersey in 1763 and earned a master's degree there in 1766. He began practicing law in 1769. From 1776 to 1783, Paterson was attorney general of New Jersey. Paterson served as a U.S. senator in 1789 and 1790. He helped draft the Judiciary Act of 1789, which set up the federal court system. Paterson served as governor of New Jersey from 1790 to 1793. He was appointed an associate justice of the Supreme Court of the United States in 1793. Richard D. Brown

Pathology, *puh THAHL uh jee,* is the study of disease, or any condition that limits the power, length, or enjoyment of life. *Comparative pathology* compares human diseases with those of animals. *Human pathology* is a branch of medicine. Pathologists use modern instruments and methods, such as electron microscopy, to recognize the changes caused by disease in the tissues and organs of the body. They try to explain why a diseased body acts differently from a normal body.

Pathologists use their knowledge of diseased tissues and body fluids to aid the physician. Pathological tests help physicians diagnose a disease and the extent of its attack. These tests may include examination of the blood, urine, and tissues. The use of laboratory tests to diagnose disease is called *clinical pathology.*

Pathologists also study diseased parts removed by surgery. They may examine corpses to learn the exact cause of death. This examination is called an *autopsy,* or *post-mortem examination.*

Special kinds of pathology study diseases of separate organ systems. For example, *neuropathology* concerns diseases of the nerves. Thomas P. Monath

Patmos, *PAT muhs* or *PAT mahs,* is a small volcanic island in the Aegean Sea, off Turkey's west coast. It is one of the Dodecanese Islands (see **Greece** [terrain map]). It was on Patmos that the author of the Book of Revelation saw his prophetic visions (see **Revelation, Book of**). The island covers 13 square miles (34 square kilometers) and has a population of 2,500. Almost all of the people depend for a living on tourism or the growing of citrus fruit and olives. Patmos was ruled by Turkey from 1537 to 1912, when Italy gained control. It was formally given to Italy by the Treaty of Lausanne, in 1923. It was given to Greece in 1947. John J. Baxevanis

Paton, *PAY tuhn,* **Alan** (1903-1988), was a South African author, social critic, and educator who wrote about the tragic consequences of rigid racial segregation. He became best known for his novel *Cry, the Beloved Country* (1948). The book tells of a struggle for human dignity amid racial conflicts in South Africa's gold mines, shantytowns, and law courts. *Too Late the Phalarope* (1953) is a novel about a sexual encounter between a white man and a black woman, then forbidden by South African law. *Tales from a Troubled Land* (1961) is a collection of short stories.

Paton, who was white, wrote several nonfiction books about South Africa's racial problems. He also wrote two autobiographies, *Towards the Mountain* (1980) and *Journey Continued* (1988).

Paton was born in Pietermaritzburg, South Africa. He became principal of the Diepkloof Reformatory for African boys, near Johannesburg, in 1935. He left in 1948 after instituting many reforms. Paton was a founder of what became the Liberal Party, an organization dedicated to attaining racial freedom through nonviolent means in South Africa. Michael Seidel

Patriarch, *PAY tree ahrk,* was the father or ruler of a family or tribe in ancient times. Abraham, Isaac, and Jacob were the patriarchs of the nation of Israel. Later, the president of the *Sanhedrin,* the highest governing council of the Jews, held the title of patriarch.

The early Christians used the title to honor the bishops of the largest and most important churches. The bishops of Rome, Alexandria, and Antioch were recognized as patriarchs in the early 300's. By the early 500's, the bishops of Jerusalem and Constantinople had come to be called patriarchs. In the Roman Catholic Church, the pope has the title *patriarch of the West.* Roman Catholic archbishops in some cities still hold the honorary title of patriarch. For example, cardinals hold the title in Alexandria and Antioch. The heads of some Eastern Orthodox Churches are called patriarchs. All Eastern Orthodox Churches regard the patriarch of Constantinople, called the *Ecumenical Patriarch,* as their spiritual leader. Ralph W. Quere

Patricians, *puh TRIHSH uhnz,* were aristocrats of the early Roman Republic (509-264 B.C.). The word *patrician* comes from the Latin word *pater* (father), which was used to describe members of the Roman Senate. Patricians belonged to wealthy families and were proud of their distinguished ancestors. They controlled the government, army, and state religion. They resisted attempts of the *plebeians* (commoners) to share their power. Until 445 B.C., a plebeian was not allowed to marry a patrician.

The two classes struggled for power for more than 200 years. During this time, the plebeians increased in

numbers and in wealth, and the number of patricians grew smaller. The patricians were forced to allow plebeians to hold more and higher positions. By 287 B.C., they could hold almost any civil or religious office, and could pass laws that affected everyone. The patricians and wealthy plebeians joined to form a new nobility, based on descent from high state officials.

Many patrician families died out between 133 B.C. and 27 B.C., the year the Roman Republic ended. Many emperors created new patricians, but the title was only an honor and carried no privileges. D. Brendan Nagle

Patrick, Saint (about 389-461), is the patron saint of Ireland. Patrick was chiefly responsible for converting the Irish people to Christianity. He became known as the Apostle to the Irish. His name in Latin is Patricius.

His life. Patrick was born in Britain. His father was a wealthy alderman and a Christian. When Patrick was 16 years old, pirates captured him during a raid and sold him as a slave in Ireland. He served as a shepherd of an Irish chieftain in Ulster. During his captivity, Patrick dedicated himself to religion. He escaped after six years of slavery and returned to his home in Britain.

As a result of his experiences in Ireland, Patrick became driven by the idea of converting the Irish to Christianity. To prepare himself for that task, he studied in the monastery of Lérins, on an island off the southeast coast of France. Patrick also went to Auxerre, France, and studied religion under Saint Germanus, a French bishop. Partly because Patrick's earlier education was inadequate, his religious superiors were reluctant to let him return to Ireland as a missionary. But Palladius, the first Irish missionary bishop, died in 431. Pope Celestine I then sent Patrick to Ireland.

Detail of *The Baptism of the King of Cashel by St. Patrick* (about 1763), an oil painting on canvas by James Barry; Terenure College, Dublin

Saint Patrick, the patron saint of Ireland, was responsible for converting the Irish people to Christianity. This painting shows Patrick, *right,* converting an Irish chieftain.

Patrick began his work in northern and western Ireland, where no one had ever preached Christianity. He gained the trust and friendship of several tribal leaders and soon made many converts. Patrick is said to have founded more than 300 churches and baptized more than 120,000 people.

Patrick brought clergymen from England and France for his new churches. He succeeded in his mission in Ireland, even though many British clergymen opposed him and the way he organized his churches. Patrick preached in Ireland for the rest of his life.

His writings serve as the most important sources of information about Patrick's life and work. During his later years, he wrote *Confession,* an account of his spiritual development. Patrick wrote this book to justify his mission to Ireland. In the book, Patrick expressed his humility and thankfulness that God called him to serve the Irish. Patrick also wrote *Letter to Coroticus.* In this letter, he criticized a raid on Ireland conducted by Coroticus, a British chieftain. Several of Patrick's converts were killed during the raid. The letter also shows Patrick's resentment of the scornful attitude of British clergymen and nobility toward the Irish.

Legends about Patrick. Many stories about Patrick are based only on legend. One of the best-known tales tells how he charmed the snakes of Ireland into the sea so they were drowned. According to another legend, Patrick used a three-leaf shamrock to illustrate the idea of the Trinity. Many people believe the shamrock came to be the traditional symbol of Ireland as a result of this legend. Today, Irish Catholics throughout the world celebrate Saint Patrick's Day on his feast day, March 17 (see **Saint Patrick's Day**). William J. Courtenay

Patrick Air Force Base, Florida, is the home of the United States Air Force's Eastern Space and Missile Center. The base covers about 2,300 acres (930 hectares) south of Cape Canaveral. The Eastern Space and Missile Center manages the Eastern Test Range, which extends southeast across the Atlantic Ocean into the Indian Ocean. There, the Eastern Test Range joins with the Western Test Range. The two ranges use electronic sensors on islands and ships to track rocket launches and orbiting vehicles.

Patrick Air Force Base was established in 1940 as the Banana River Naval Air Station. During World War II (1939-1945), it served as a base for antisubmarine patrol planes. It was transferred to the Air Force in 1948 and renamed after Major General Mason M. Patrick, who was chief of the Army Air Corps in the 1920's.

Patriotism is the love of one's country. It includes attachment to the country's land and people, admiration

for its customs and traditions, pride in its history, and devotion to its welfare. The term suggests a feeling of oneness and membership in the country.

Patriotism has existed in all ages and among most peoples. Evidence of patriotism can be found in the art, literature, and music of many countries. Many artistic masterpieces glorify a country's leaders, historical events, and scenery. Numerous literary works praise love of country and willingness to suffer even death in defense of a country's freedom and good name. Patriotic songs and slogans have helped unite citizens in support of their country during periods of war, revolution, or economic development.

Schools help develop patriotism by creating an appreciation for common memories, hopes, and traditions. Through the study of history, for example, many students learn to love their country and admire its heroes. Patriotic organizations maintain and promote such symbols of patriotism as the national anthem, national flag, and national shrines and monuments. Leading patriotic organizations in the United States include the American Legion and the Veterans of Foreign Wars. *World Book* has separate articles on these and many other patriotic organizations. See **Veterans' organizations** with its list of related articles.

Most people agree that patriotism involves serving one's country, but many disagree on how they can best perform such service. Some say that the national government speaks for the country and that citizens should therefore actively support all government policies and actions. Others argue that a true patriot will speak out if convinced that the country is following an unjust or unwise course of action.

Foundations of patriotism. The word *patriotism* comes from a Greek word that means *fatherland.* Throughout most of history, love of fatherland or homeland was simply a love for the physical features of the land, including mountains, plains, and rivers. But the idea of patriotism has changed since the 1700's, in part because of the rise of such political ideals as democracy and Communism. For example, many people believe strongly in the democratic ideal, according to which people have a right to govern themselves. These people may have strong patriotic feelings because they live in a democratic country and support its institutions.

Patriotism has also changed since the 1700's because of the rise of *nationalism.* Nationalism is a people's sense of belonging together as a nation. Here, the word *nation* refers to a group of people who share a common culture, history, or language and have a feeling of unity. But the boundaries of a nation do not necessarily match the boundaries of a country or state. A *country* is an area of land whose people have an independent government. The people of a nation may be ruled by the governments of more than one country, and a single country may contain people of more than one nation.

In some cases, strong feelings of nationalism contribute to patriotism. If people feel that their country represents them as a nation and reinforces their common culture, their nationalistic feelings often include patriotism. This is especially true in the case of a *nation-state,* which exists when a nation and a state or country have the same boundaries.

However, nationalism may conflict with patriotism when the people of a nation do not identify with the country that rules part or all of their homeland. For example, many of the African countries that gained independence in the mid-1900's were established with the same boundaries as earlier European colonies. Many of these boundaries cut across the homelands of African ethnic groups. As a result, people of these groups may feel closer ties to neighbors in another country than to other groups in their own country.

Abuses of patriotism. Patriotism, like other emotional attitudes, sometimes becomes exaggerated or distorted. People who are excessively attached to a certain country are sometimes called *superpatriots.* An unreasoning enthusiasm for the military superiority and glory of one's country is called *chauvinism* or *jingoism* (see **Jingoism**).

Exaggerated or distorted forms of patriotism have existed in almost all countries. In the late 1800's, the French and British believed they had a moral responsibility to establish colonies in Asia and Africa, and thus bring the benefits of their culture to their "inferior brothers." In the 1900's, the Germans under Adolf Hitler and the Italians under Benito Mussolini became convinced their countries had a patriotic mission to extend their territorial boundaries.

Demands for public demonstration of loyalty to a country are often heard in times of crisis. During World War I (1914-1918), for example, the loyalty of Americans of German ancestry was questioned in the United States. During World War II (1939-1945), thousands of patriotic Japanese-Americans were placed in detention camps because of unreasonable fears that they might be loyal to Japan rather than to the United States.

The concept of patriotism has often been distorted by a government or a person for selfish gain. After World War II, for example, the government of the Soviet Union denied Soviet citizens a right to leave the country, on the grounds that a patriotic person would not wish to do so. In the United States during the 1950's, U.S. Senator Joseph McCarthy charged that Communists had infiltrated the U.S. government. In his charges, he strongly questioned the patriotism of numerous government officials and accused them of treason. Many historians believe McCarthy used the issue of patriotism to help boost his political career. Karen A. Cerulo

Patronage, *PAY truh nihj,* in politics is the power to name appointees to government jobs. In the United States, the president and various state and local officials can appoint people to certain positions. Appointments are usually suggested by national and state politicians. They often use patronage to reward those who worked for them in political campaigns. Such a use of patronage is called the *spoils system* (see **Spoils system**).

Patrons of Husbandry. See Grange, National.

Patroon system, *puh TROON,* was a plan set up by the Dutch West India Company in 1629. It was used to colonize New Netherland, in what are now the states of New York, New Jersey, Delaware, and Connecticut. Any member of the company who paid to bring over 50 settlers within four years could have a large tract of land. The settlers had to be at least 15 years old. The *patroon* (owner of the land) became a kind of feudal lord who controlled all aspects of the settlers' lives, including their right to move, go into business, or even marry.

Five patroonships were granted. But only Rensselaerswyck, the Van Rensselaer manor, lasted into the 1700's. The system failed because few people were willing to give up their personal freedom permanently. Other land policies of the company contributed to the failure of the patroon system. For example, the company offered free land in New Netherland to settlers who paid their own passage to America. Later, the company even paid the passage to attract settlers. Joan R. Gundersen

Patton, George Smith, Jr. (1885-1945), was one of the most colorful American generals of World War II. His dramatic manner, outspoken comments on military and political affairs, and reckless behavior won him both applause and criticism. His toughness and rough speech earned him the nickname "Old Blood and Guts."

African invasion. In November 1942, Patton led the Western Task Force ashore in Morocco in the Allied invasion of North Africa. In March 1943, he took command of the Second U.S. Army Corps and won one of the first major U.S. victories of the war at El Guettar. Before the Tunisian campaign ended, Patton took command of the Seventh Army for the invasion of Sicily in July 1943. In 39 days, his army and the British Eighth Army captured the island. But an event soon after that nearly wrecked Patton's career. While inspecting army hospitals, he slapped two soldiers who were suffering from battle fatigue. One of the soldiers also had malaria. Patton explained that he thought the soldiers were only pretending. General Dwight D. Eisenhower forced Patton to apologize, and Congress temporarily held up his permanent promotion to major general. Patton's usefulness was seriously harmed for several months.

U.S. Army

George S. Patton, Jr.

Victory in France. In January 1944, Patton became commander of the Third Army for the French campaign. When the First Army broke through at St. Lô, Patton's forces poured through in the first of an amazing series of advances. They went so far ahead of their supplies that they had to be provisioned by plane. His forces crossed France, reaching Metz by autumn, and fought in the Battle of the Bulge near Bastogne, Belgium, in December 1944.

As Germany collapsed, the Third Army drove across southwestern Germany into Czechoslovakia and Austria. When the Germans surrendered, Patton's army held a large part of what became the American occupation zone. Patton became a full general. After May 1945, he took command of the occupation troops in the American zone. But, in talking with reporters, he compared the Nazis to the losers in an American political election. These comments got him in trouble again with the press and his superior officers. Eisenhower transferred him to the command of the Fifteenth Army, a headquarters set up to interview captured German generals and prepare materials for the official history of the war. In December 1945, Patton died of injuries from a car accident. He was buried in a Third Army cemetery in Luxembourg.

Early life. Patton was born on Nov. 11, 1885, in San Gabriel, California. He was graduated from the U.S. Military Academy in 1909. An excellent athlete, he placed fifth in the 1912 Olympic pentathlon. Patton entered the cavalry after graduation, and served in the 1916 Mexican expedition. In World War I, he commanded a tank brigade in France. James L. Stokesbury

Paul I (1901-1964) was king of Greece from 1947 to 1964. He succeeded his brother, George II, as king during a civil war between Greek Communists and people who supported the monarchy. With his wife, Queen Frederika, Paul tried to make the Greek monarchy a protector of democracy and a supporter of all classes of Greek society. From 1917 to 1920, Paul lived in exile with his father, King Constantine I. From 1923 to 1935 and from 1941 to 1946, he lived in exile again, this time with George II. Paul was born in Athens, and was trained as a naval officer. John A. Koumoulides

Paul III (1468-1549) was elected pope in 1534 and reigned during the transition in Rome from the Renaissance to the church renewal movement called the Counter Reformation. While in many respects a Renaissance prince, Paul devoted serious attention to religious matters and helped further church reform. He named prominent theologians and churchmen to the college of cardinals, and he encouraged the development of new religious orders, notably the Society of Jesus, commonly called the Jesuits. In 1545, he convened the Council of Trent, which played a major role in the Counter Reformation (see Trent, Council of).

Paul was born in Canino, Italy, near Viterbo. His given and family name was Alessandro Farnese. Like many other Renaissance popes, he promoted the interests of his powerful family. He was an important patron of the arts, commissioning the completion of the elegant Farnese Palace and Michelangelo's painting *The Last Judgment* in the Sistine Chapel. Charles L. Stinger

See also Pope (Renaissance and Reformation).

Paul IV (1476-1559) was elected pope in 1555. He reflected the most repressive tendencies of the church renewal movement called the Counter Reformation. Paul was harsh and intolerant and rejected any reconciliation with Protestantism during the Reformation. He de-

nounced the religious settlement of the Peace of Augsburg (1555) for recognizing Lutheranism in Germany. Paul viewed any deviation from rigid orthodoxy with suspicion. He greatly extended the activities of the Inquisition, and the first Index of Forbidden Books was given official status in 1557. See **Ghetto; Inquisition; Index of Forbidden Books.**

Paul was born near Benevento, Italy. His given and family name was Gian Pietro Carafa. He was personally ascetic and in 1524 he helped found the Theatines, a monastic order dedicated to a life of poverty and to church reform. Paul became a cardinal in 1536 and led the church reform party in Rome. Beginning in 1550, he headed the Roman Inquisition, gaining a reputation for unyielding severity. Charles L. Stinger

Paul VI (1897-1978) was elected pope of the Roman Catholic Church in 1963. He immediately pledged to continue Vatican Council II, called by John XXIII, the previous pope. Paul presided over the council, which ended in 1965 and which brought widespread reforms to the church. See **Vatican Council II.**

In 1964, Paul traveled to Jerusalem, where he met with the ecumenical patriarch of Constantinople, Athenagoras I. The Eastern Orthodox Churches give the highest honor to this official. At the Vatican Council, the two leaders issued a joint statement removing the excommunications issued by the Eastern and Western churches against each other in 1054. In 1965, Paul flew to New York City—the first papal visit to the United States—to plead to the United Nations for world peace.

Paul wrote several *encyclicals* (pastoral letters). They dealt mainly with dialogue among Catholics, non-Catholics, and non-Christians and with the need for social justice within nations and between richer and poorer nations. But Paul is perhaps best remembered for *Humanae Vitae* (*On Human Life*), issued in 1968. This encyclical upheld the church's traditional prohibition against artificial means of birth control.

During his reign, Paul was often criticized as an extreme conservative. Today, many church historians consider him far more moderate than his critics recognized. After Vatican Council II, Paul had to skillfully steer the church on a middle course between liberals and conservatives. The liberals wanted to reform the church further than Paul thought was possible, while the conservatives rejected the council's reforms altogether.

Paul was born in Concesio, Italy, near Brescia. His given and family name was Giovanni Battista Montini. He was ordained a priest in 1920. After graduate studies in Rome, Paul served in the papal secretariat of state, with only a brief interruption, from 1922 to 1954. In 1954, he was appointed archbishop of Milan. John XXIII made him a cardinal in 1958. Gerald P. Fogarty

Paul, Alice (1885-1977), became one of the first American leaders of the movement for equal rights for women. She was sometimes called the mother of the Equal Rights Amendment to the U.S. Constitution.

Paul was born in Moorestown, N.J. She received a Ph.D. degree in social work from the University of Pennsylvania in 1912 and earned three law degrees during the 1920's. From 1907 to 1910, Paul worked with British women in their struggle to obtain the right to vote. After returning to the United States, she organized protest marches calling for the government to grant voting rights to women. The 19th Amendment, which gave women the right to vote, became part of the Constitution in 1920.

In 1913, Paul formed the National Woman's Party, which supported equal rights for women. She submitted the first version of the Equal Rights Amendment to Congress in 1923. Paul worked with international women's organizations in the 1930's and founded the World Woman's Party in 1938. June Sochen

Paul, Saint, was one of the most important leaders of early Christianity. He became famous as a missionary and a founder of congregations throughout Asia Minor and southeastern Europe. His letters, called *epistles,* to his followers form a significant part of the New Testament. Because of his importance, Paul is sometimes referred to as an "apostle," though he was not one of the 12 apostles of Jesus Christ.

Early life. Paul, a Jew by birth, was born a few years after the birth of Jesus. Paul was born in Tarsus, a city in Cilicia (now part of Turkey). His original name was Saul. He grew up exposed to both his family's Jewish religious heritage and the non-Jewish culture around him. As a youth, Paul went to Jerusalem and studied under the famous rabbi Gamaliel.

In Jerusalem, Paul met Jews who had become Christians. They believed that Jesus, who recently had been crucified, was the *Messiah,* the promised savior of the Jews. Paul began to persecute these Jews because he found their beliefs and behavior contrary to the traditions of his people. But one day, while traveling to Damascus, Paul encountered the risen Christ. This experience impressed Paul so greatly that he soon became a Christian.

Missionary career. Paul's work in bringing Christianity to *gentiles* (non-Jews) shows his tremendous energy and dedication. He is often called the "Apostle to the Gentiles." Immediately after Paul's conversion, he went to an area of Arabia that is now in Jordan, and then to Syria and Cilicia. Historians know little about Paul's life as a missionary during the next 15 years.

The most productive period of Paul's career began shortly before A.D. 50. The Acts, a book of the New Testament, describes Paul's three journeys as a missionary during this period. On his first journey, Paul sailed to the island of Cyprus with two of his followers, Barnabas and Mark. He and Barnabas then crossed to the southern coast of Asia Minor. The story of this journey describes Paul's technique as a missionary. He moved quickly from place to place, preaching first in synagogues and then to gentiles. He gave bold, controversial speeches that angered many people. As a result, Paul was frequently mistreated and occasionally imprisoned.

Two other followers, Silas and Timothy, accompanied Paul on his second missionary journey. On this trip, Paul traveled to northwest Asia Minor. He then crossed to Macedonia, thus bringing Christianity to Europe. Later

Saint Paul made three important missionary journeys during the late A.D. 40's and 50's. He preached in Asia Minor and brought Christianity to Macedonia and Greece. On a fourth trip, he was sent as a prisoner to be tried in Rome.

WORLD BOOK map

on this journey, Paul visited such Greek cities as Thessaloniki and Corinth. Paul's third missionary journey covered much of the same territory as his second trip.

Later years. After Paul returned to Jerusalem, he was arrested because of opposition from hostile Jews. He spent two years in prison and then demanded his right as a Roman citizen to have a trial in the emperor's court. Paul was sent to Rome, where he remained a prisoner for two more years. He apparently died in Rome sometime after A.D. 60. His feast day is June 29.

Paul's letters and ideas. The letters written by Paul helped him keep in touch with his followers. They date from a period between A.D. 50 and the early 60's and are the earliest books of the New Testament. Paul wrote Romans, First and Second Corinthians, Galatians, Philippians, First and Second Thessalonians, and Philemon. He probably also wrote Colossians and may have written Ephesians, First and Second Timothy, and Titus. The Epistle to the Hebrews, once credited to Paul, is now considered the work of another writer.

Paul viewed Christianity primarily in relation to Judaism. He felt that the history of the Jews and the writings of the Old Testament had prepared humanity for Christianity. Nevertheless, Paul regarded the Christian faith—or "life in Christ," as he called it—as something new. In Judaism, God and human beings were related chiefly through the *Torah,* the first five books of the Old Testament. The Torah expressed God's will and informed people of their responsibilities to Him.

Paul believed the death and Resurrection of Jesus opened a new kind of relationship between God and human beings. He was certain that gentiles, who did not know or understand the Torah, could benefit from this new relationship, which he called *justification.* Justification resulted not from something that human beings did, such as obey the Torah, but from something that God had done. In Jesus, God had given humanity a gift. Paul felt that this gift put God and people into their proper relationship, which human effort alone never could have done. To Paul, justification was central to Christianity.

By means of his letters, Paul encouraged early Christians in times of discouragement and persecution. He reminded his followers of their responsibilities to one another and thus provided many basic ideas of Christianity. Christians recognized Paul's importance by preserving his letters and making them a central part of the New Testament. David B. Burrell

Pauli, *PAW lee,* **Wolfgang** (1900-1958), an Austrian theoretical physicist, won the 1945 Nobel Prize in physics for his proposal in 1925 of a rule explaining the behavior of electrons in atoms. Such electrons orbit the nucleus of the atom. The rule, now called the *Pauli exclusion principle,* holds that no two electrons in an atom can have the same *quantum numbers.* An electron in an atom has four such numbers. They define the energy of the electron in terms of the distance of its orbit from the nucleus, the orbit's shape, the orientation of the axis of the orbit, and the electron's spin on its own axis.

Pauli's principle was a key new idea. In 1913, Danish physicist Niels Bohr had published a theory describing how the single electron of the hydrogen atom moves around the nucleus. Pauli's discovery enabled scientists to picture the atomic structure and the behavior of the electrons of every known chemical element. Because the behavior of an atom's electrons determines how it will take part in chemical reactions, the principle also explained the chemical characteristics of the elements.

Pauli also explained the loss of energy and *angular momentum* (a measurement of spin) in certain atom-smashing experiments. In 1930, he proposed the existence of a subatomic particle, now called a *neutrino,* that has the "missing" energy and momentum. See **Neutrino.**

Pauling, Linus Carl (1901-1994), an American chemist, won two Nobel Prizes. He received the 1954 Nobel Prize in chemistry and the 1962 Nobel Peace Prize.

Pauling won the chemistry prize for his research on the nature of chemical bonds. He showed that a knowledge of the way atoms are linked helps explain the structure of complex molecules. Pauling began his research by studying the structure of crystals. He analyzed the way atoms in a crystal *diffract* (spread out) X rays as the rays pass through the crystal. Pauling combined his findings with the theories of *quantum mechanics* about the arrangement of electrons within an atom and the ways in which atoms share and exchange electrons (see Quantum mechanics). In this way, he calculated the energies that bind atoms, the distances between the atoms, and the angles at which the bonds form.

Much of Pauling's research involved the study of *amino acids,* the organic compounds that make up proteins. His work contributed greatly to an understanding of the complex molecular structure of proteins. It also led to new knowledge about *sickle cell anemia,* a disease of the red blood cells. Pauling later attracted attention for his experiments on the use of vitamin C in treating cancer and the common cold.

Pauling won the Nobel Peace Prize for his efforts to ban nuclear weapons, especially his campaign against nuclear weapons testing. In 1958, he submitted a petition to the United Nations (UN) that stated in part: "Each added amount of radiation causes damage to the health of human beings all over the world." More than 11,000 scientists from 49 countries signed the petition. It helped lead to the signing of a treaty in 1963 that outlawed nuclear tests in the atmosphere, in outer space, and underwater—but not underground. Most UN members signed the treaty.

Pauling was born in Portland, Oregon. He received a Ph.D. degree from the California Institute of Technology in 1925. Edward E. Daub

Paulists are members of the first Roman Catholic order of priests to be founded in America. Isaac Thomas Hecker, an American priest, founded the order in New York City in 1858. Its full name is the Society of Missionary Priests of St. Paul the Apostle. Hecker founded the Paulists as a community of priests dedicated to Americanizing immigrant Roman Catholics and carrying Catholicism to non-Catholic Americans. Today there are only about 250 Paulists in the United States, Canada, and Rome. Despite their small numbers, the Paulists have been influential, especially through their effective use of print media, radio, and television. David G. Schultenover

He found that, by repeated association, an artificial stimulus (such as a bell) could be substituted for a natural stimulus (food) to cause a physiological reaction (salivation). He called this a *conditioned reflex.* Pavlov believed that all acquired habits, and even higher mental activity, depend on chains of conditioned reflexes.

Pawnbroker is a person who lends small sums of money on articles of clothing, watches, jewelry, and

other belongings that are left with the pawnbroker as security. The articles that are left are *pawned.* The pawnbroker has the right to sell these articles if the loan is not repaid with interest and charges within a certain time after the debt becomes due.

The pawnbroker usually limits the loan to a small fraction of the value of the article, which provides security for the loan. For this reason, pawnshop customers do not usually regard the transaction as a sale of their goods. Customers pay back the loan with high interest to redeem their property. The pawnbroker is sometimes called the poor person's banker. He or she makes it possible for a person without employment or in financial distress to obtain credit quickly, even in a strange city. Pawnshops are disappearing from many areas due to the widespread availability of credit cards, which provide easy access to small loans at lower interest rates.

Pawnbroking dates back to the time when there were no banks. Many American cities had pawnshops as early as 1800. But the business was not generally recognized throughout the nation by law until the late 1800's. Then laws were passed by states and cities to curb abuses, such as unfair charges. In most cases, state laws restrict the maximum interest rates pawnbrokers may charge.

In general, regulations require the pawnbroker to keep a record book. It contains a description of every article received. This book must be submitted upon request to the police or other authorities who may be looking for stolen goods. The pawnbroker is not allowed to receive goods from anyone under the influence of liquor, or from anyone under a specified age.

Three golden balls, an old trade sign of the pawnbroker, usually hang outside the pawnshop. They originated with the moneylenders of Lombardy in Italy, who were important bankers in medieval England. The three golden balls were also the coat of arms of the Medici family, the richest merchants and moneylenders of Florence. Carol S. Greenwald

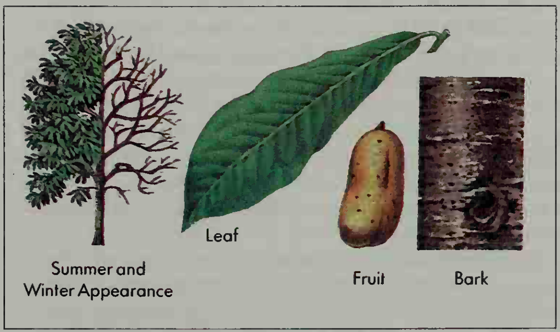
Pawnee Indians, *paw NEE,* are a tribe that lives largely in the Pawnee, Okla., area. Many young members of the tribe have government jobs.

The Pawnee once lived in what is now Nebraska. Most of the year they lived in villages and raised corn, beans, and squash. The villages consisted of 10 to 12 large, round, earth-covered houses. The Pawnee left their villages once or twice a year to hunt buffalo on the plains. During the hunting season, they lived in tepees made of buffalo skins. Pawnee men shaved their heads except for a small scalp lock. They stiffened the scalp lock with grease and paint so that it stood up like a horn.



Religion played an important role in Pawnee life. The Pawnee regarded corn as a sacred gift, and many of their religious ceremonies centered around corn. Other ceremonies involved buffalo hunting and war. One Pawnee ceremony involved human sacrifice. But in 1838, opposition from within the tribe ended the practice.

A treaty signed in 1857 between the Pawnee and the United States restricted the tribe to a reservation along the Loup River in Nebraska. In 1875, because of pressure from white settlers and attacks by other tribes, the Pawnee moved to the Indian Territory (now Oklahoma).

Today, the Pawnee are governed by two groups. The Pawnee Tribal Business Council handles the tribe's business and financial matters. Any council action regarding tribal membership or treaties is subject to approval by the Nasharo (Chiefs) Council. Jen Shunatona Cale

Pawpaw is a small tree or shrub native to North America. The tree produces a fruit, also called *pawpaw,* that looks somewhat like a thick, short banana. The plant is found in the southern United States, and as far north as Kansas, Michigan, and New Jersey. Its leaves spread out in umbrellalike whorls. When the leaves are bruised they give off a disagreeable odor.

The pawpaw grows from 10 to 40 feet (3 to 12 meters) high and bears fruit 2 to 6 inches (5 to 15 centimeters) long. The fruit has yellowish-green or greenish-brown skin and a yellowish or greenish-white flesh. Those with yellowish flesh have a pleasant taste and are often eaten fresh. Those with greenish-white flesh generally are not eaten. The wood of the tree is too soft and coarse to be valuable.

It covers nearly 9 square miles (23 square kilometers) on either side of the Blackstone River. It is part of the Providence-Fall River (Massachusetts)-Warwick metropolitan area. For location, see **Rhode Island** (political map).

Samuel Slater, an English textile worker, set up the first cotton-spinning mill powered by water in the United States in Pawtucket in 1790. Today, the city's leading industries produce wire, cable, and jewelry. Pawtucket is the home of Hasbro, the largest toy manufacturer in the United States. The city also has factories for bleaching and dyeing cotton, for making cotton thread, and for weaving rayon goods. Machine shops produce machine tools, rolled steel, pressed metal products, hardware, nuts, bolts, and insulated wire. Other products made in Pawtucket include lace, shirts, hosiery, braid, chemicals, cement, paper and wood products, sports equipment, dental supplies, and computer-related items.

The original village was founded in 1671 by Joseph Jenks, Jr., an ironworker. The part of the city that lies on the east bank of the Blackstone River belonged to Seekonk, Massachusetts, until 1862. The section on the west bank of the river was part of North Providence until 1874. The two villages became the town of Pawtucket. A city charter was granted in 1885. Pawtucket has a mayor-council government. Stanford E. Demars

Payne, John Howard (1791-1852), was the first American playwright to achieve international fame. However, he is best known for writing the words of the song "Home, Sweet Home." This song first appeared in his play *Clari, or the Maid of Milan* (1823).

Payne was born in New York City. His first play, *Julia, the Wanderer* (1806), was performed there when he was only 14 years old. At 17, Payne made his debut as an actor. He went to London in 1813 and lived there and in Paris until 1832. In London, Payne tried to establish himself as an actor but failed. He soon turned to playwriting.

Many of Payne's plays were unsuccessful, and he spent most of his life in debt. But he did achieve some popularity with his tragedy *Brutus, or the Fall of Tarquin* (1818) and other dramas. In 1823, while in London, Payne worked with the American writer Washington Irving on *Charles the Second, or The Merry Monarch* and several other productions.

Payne returned to the United States in 1832 and later became interested in the problems of American Indians. In 1835, he met with leaders of the Cherokee and published two letters in the *Knoxville* (Tennessee) *Register.* In the letters, he tried to persuade Congress to let the Cherokee continue living in the Southeast. His efforts failed. Payne served as U.S. consul in Tunisia from 1842 to 1845 and from 1851 until his death. Edward W. Clark

Payne-Gaposchkin, *PAYN guh PAHSH kuhn,* **Cecilia Helena** (1900-1979), was an English-born astronomer who became an authority on *variable stars* (stars that change in brightness) and the structure of the Milky Way Galaxy. She was one of the first women to advance to the rank of professor at Harvard University and the first woman to head a department there.

Cecilia Payne was born in Wendover. She graduated from Cambridge University in England in 1923. Later that year, she went to Cambridge, Massachusetts, where she studied at Radcliffe College and worked extensively at Harvard College Observatory. In 1925, she became the first woman to earn a doctorate in astronomy from Radcliffe. Her early work dealt with atmospheres of stars.

In 1934, Payne married the Russian-born Harvard astronomer Sergei Gaposchkin. They worked together on many variable star projects. Payne-Gaposchkin was a professor of astronomy at Harvard from 1956 to 1966. She was chairman of Harvard's Department of Astronomy from 1956 to 1960. Barbara L. Welther

Payton, Walter (1954-1999), a running back for the Chicago Bears, became the leading rusher in National Football League (NFL) history. In 1984, Payton broke Jim Brown's 12,312-yard career rushing record. He retired after the 1987 season with a career rushing total of 16,726 yards. In 1977, Payton rushed for 275 yards against the Minnesota Vikings, an NFL single-game record until Corey Dillon of the Cincinnati Bengals rushed for 278 yards in a game against the Denver Broncos in 2000. Payton stood 5 feet 10 inches (1.8 meters) tall and weighed about 200 pounds (90 kilograms). He was a strong, durable, versatile runner and pass receiver.

Walter Jerry Payton was born in Columbia, Mississippi. He was a star running back at Jackson State Univer-

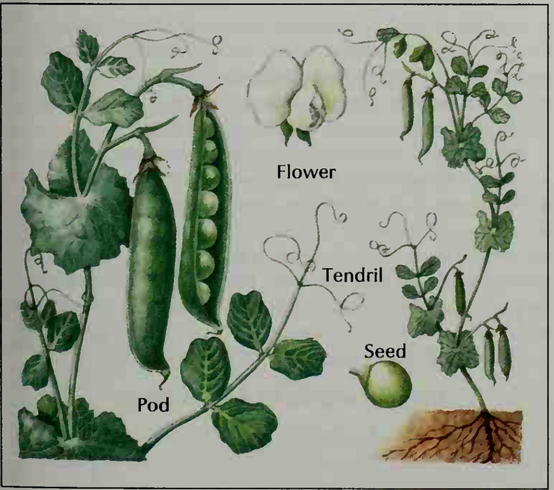
Paz, *pahs,* **Octavio,** *awk TAH vyoh* (1914-1998), a Mexican poet and essayist, won the 1990 Nobel Prize for literature. He was the first Mexican author to receive the prize. Paz's works reflect a range of influences, including Aztec mythology, Marxism, Asian philosophy, surrealism, and symbolism. Paz's collection *Liberty Under Oath* (1960) consists of poems written between 1935 and 1957. *The Collected Poems of Octavio Paz, 1957-1987* (1987) includes his well-known "Sunstone." This poem uses contrasting images to symbolize the inevitable loneliness of individuals and their search for union with others.



Paz wrote essays on many subjects, including anthropology, literature, philosophy, and science. *The Labyrinth of Solitude* (1950) is a collection dealing with the character of the Mexican people. In "The New Mexico" (1970), Paz analyzed civilization, language, and political protest. *El Mono Gramático* (1972) combines essay, narration, and poetry to give his views on life and art. His reflections on modern history appear in *One Earth, Four or Five Worlds* (1985). His essays on modern poetry were collected in *The Other Voice* (1991).

Paz was born in Mexico City. From 1962 to 1968, he served as Mexico's ambassador to India. Dick Gerdes

Pea is a plant grown chiefly for its round edible seeds, which are also called peas. Cooked peas are a popular food. People also add peas to soups, salads, and casseroles. Peas are also used as feed for livestock. Peas are a good source of protein and vitamins A and C.

Pea plants have vines with soft stems that measure 6 inches to 6 feet (15 to 182 centimeters) long. Each leaf consists of one to three pairs of leaflets, and it ends in a curly thread called a *tendril.* Most pea plants have white flowers. Some have reddish-purple blossoms. Pea plants bear pods that contain four to nine or more seeds.

Peas belong to a large family of plants called *legumes,* which produce pods. Other legumes include beans, peanuts, and alfalfa. See **Legume.**

Kinds of peas. There are two main types of peas, *field peas* and *garden peas.* Field peas have smooth, hard seeds that may be green, yellow, white, gray, blue, brown, or spotted. Some varieties of yellow and green field peas are marketed as *split peas* for making soup. Other varieties are used as fresh pasture for livestock, or are made into hay or silage. Garden peas generally have green, wrinkled seeds, though some varieties have smooth seeds. Garden peas are sweeter and softer than field peas and are popular with home gardeners. Varieties known as edible-podded peas are eaten with the pods and are often used in Asian cooking.

Growing peas. The pea plant is an *annual*—that is, it must be replanted each year. Peas require rich soil, constant moisture, and a cool growing season to develop well. In North America, most peas are grown in the northern United States and in Canada. Peas are planted in early spring and are harvested 60 to 70 days later.

Field peas are usually planted with a *grain drill,* a machine that drops the seeds and covers them with soil. They are harvested with a combine. Garden peas are usually planted and harvested by hand. They are planted 1 to 2 inches (2.5 to 5 centimeters) deep in rows 20 to 30 inches (51 to 76 centimeters) apart.

Diseases and pests. The most common diseases of pea plants are *leaf spot, stem blight, bacterial blight,* and *fusarium wilt.* Leaf spot, stem blight, and bacterial blight produce spots on the plants. Fusarium wilt restricts the growth of pea plants and makes them yellow. Scientists have developed varieties of peas that can resist these diseases. Leaf spot, stem blight, and bacterial blight can also be controlled with pesticides.

Pea plants are also attacked by such insect pests as *pea weevils, pea moths,* and *pea aphids.* Pea weevils and pea moths produce young that burrow into the pods and eat the seeds. Pea aphids damage a plant by sucking its juices and spreading virus diseases. Farmers control most of these pests with insecticides. Donald J. Reid

Scientific classification. Peas belong to the pea family, Fabaceae or Leguminosae. The scientific name for the garden pea is *Pisum sativum.* Field peas are *P. arvense.*

Peace is the state of being calm, quiet, and free of disturbance. From a military and political point of view, peace means freedom from such violent disturbances as wars and riots. It does not mean total harmony among people. Even in peacetime, people take part in such forms of conflict as debates, lawsuits, sports contests, and election campaigns.

Throughout history, most people have wanted lasting peace. Religions and philosophers have called for the peaceful settlement of disagreements. The Bible declares, "Thou shalt not kill" and "Blessed are the peacemakers." Philosophers in ancient Greece and Rome taught brotherhood and nonviolence.

Yet since earliest times, the world has seldom had a long period of unbroken peace. Through the centuries, people have probably spent at least as much time at war as at peace. This article discusses past and present attempts to achieve lasting freedom from war.

Peacemaking efforts through the years

Ancient Greece and Rome. Ancient Greece consisted of many independent regions called *city-states.* The city-states frequently waged war on one another. As a result, several of them banded together and formed an organization that made one of the first attempts to limit warfare. This organization, called the Amphictyonic League, prohibited any member from destroying another or cutting off another's water supply.

Once every four years, the Olympic Games united the city-states. A truce created temporary peace throughout Greece so the games could take place. For a month, no one could bear arms or make war.

The Roman Empire maintained peace throughout a large part of the world during a period known as the *Pax Romana* (Roman peace). This peace lasted more than 200 years, from 27 B.C. to A.D. 180. During the Pax Romana, the Roman Empire extended over much of Europe, the Middle East, and northern Africa. At that time, no other nation was powerful enough to attack the Romans.

The Middle Ages. After the Roman Empire weakened during the A.D. 400's, small wars raged throughout Europe. The Christian church became the greatest force for peace. A church custom called the Truce of God limited fighting in private disputes to certain days of the week. A ruling called the Peace of God forbade fighting in such holy places as churches and shrines. But the church permitted "just" wars, such as those in defense of Christianity or a people's homeland.

From the 1400's to the 1700's, many people proposed various plans to achieve lasting peace. In the early 1600's, for example, the French statesman Maximilien de Béthune, Duke of Sully, developed a "Grand Design" for peace in Europe. Sully's plan called for the formation of a council of representatives of all European countries. The council would settle disagreements between nations.

In 1625, the Dutch statesman Hugo Grotius proposed international rules of conduct in a book called *On the Law of War and Peace.* For example, nations should guarantee certain rights to neutral nations, which took no part in a war. Grotius' ideas formed the basis of international law (see **International law**).

The Thirty Years' War ended in 1648 with the Peace of Westphalia. This treaty tried to ensure peace by establishing a *balance of power.* Such a plan maintains an even distribution of military and economic power among nations. As a result, no nation or group of nations is strong enough to conquer any other nation or group of nations. See **Balance of power.**

About 1647, the English religious leader George Fox founded the Society of Friends, most commonly known today as the Quakers. This group believed that the teachings of Jesus Christ prohibited war. Throughout their history, the Quakers have opposed war and supported peace movements. The Quaker leader William Penn, who founded the colony of Pennsylvania, proposed a peace plan similar to Sully's "Grand Design." Penn wrote a book called *An Essay Towards the Present and Future Peace of Europe* (1693). In it, he called for an international council to settle disputes between nations.

The *Project for Perpetual Peace,* written by a French clergyman, the Abbé Charles Irénée Castel de Saint-Pierre, was published in 1713. It called for a "Senate of Europe" composed of 24 delegates from the European nations. The French philosopher Voltaire criticized this plan because the member nations would have been monarchies. Voltaire believed the world could not have peace unless all nations became democracies.

The 1800's and early 1900's. In 1815, an American businessman, David L. Dodge, formed the New York Peace Society, the nation's first organization dedicated to preserving peace. Other *pacifist* groups followed, including the American Peace Society in 1828 and the Universal Peace Union in 1866.

During the 1800's, many international conventions discussed peacekeeping. Peace conferences met in London in 1843; in Brussels, Belgium, in 1848; in Paris in 1849; and in Frankfurt (am Main), Germany, in 1850. In 1898, Czar Nicholas II of Russia called for an international meeting to discuss arms limitation. As a result, conferences took place at The Hague in the Netherlands in 1899 and 1907. These conferences did not succeed in limiting armaments. But they did establish the Permanent Court of Arbitration to handle legal disputes between nations.

The Swedish chemist Alfred B. Nobel, who invented dynamite, regretted the wartime death and injury caused by his invention. In his will, he set up a fund to award annual prizes, including one for outstanding work in promoting world peace. The first Nobel Prize for peace was awarded in 1901 (see **Nobel Prizes**).

After World War I ended in 1918, a group of 42 governments established the League of Nations. This international association had the goal of maintaining peace throughout the world. Disputes between nations would be settled by the League Council or by *arbitration,* a decision by a third party. But the League of Nations had little power, partly because the United States and some other major nations never joined. In addition, League members failed to cooperate with one another.

Current efforts to ensure peace

Since the end of World War II in 1945, many attempts have been made to assure lasting peace among all nations. The major forms of these efforts have included (1) diplomacy, (2) international organizations, (3) arms control, (4) collective security, and (5) improvement of international communication and trade.

Diplomacy involves *negotiations* (discussions) between two or more nations. Most governments have diplomats who serve as their representatives in other countries to promote international cooperation and harmony. Other peace efforts depend largely on successful diplomacy. Many political experts rate diplomacy as the most important factor in peacekeeping. See **Diplomacy**.

International organizations work for the peaceful settlement of disagreements between nations. In 1945, 50 countries created the United Nations (UN), the major international organization dedicated to world peace. The League of Nations was dissolved in 1946.

The UN Security Council investigates quarrels between nations and suggests ways of settling them. If any nation endangers the peace, the council may use economic *sanctions* (penalties) against it. For example, member nations might stop trading with the offender. If such measures fail, the council may ask UN members to furnish troops to enforce its decision. The UN has achieved some success in keeping the peace. But it has failed to prevent local wars in several regions, including Africa, Southeast Asia, and the Middle East.

Arms control involves control, reduction, or elimination of certain armed forces or weapons. In 1968, the UN approved a *nonproliferation treaty* to stop the spread of nuclear weapons. This treaty, which took effect in 1970, bars the nuclear powers from giving nuclear weapons or knowledge to other nations. The UN also won approval of arms-control treaties in the 1970's. One treaty banned the production and stockpiling of biological weapons. The United States, Russia, and other nations have agreed to observe limits on the production and possession of nuclear weapons. In 1993, over 120 countries signed a UN-sponsored treaty banning the manufacture, use, transfer, and stockpiling of chemical weapons. The treaty took effect in 1997. See **Arms control**.

Collective security resembles the balance of power system. Each member of a group of nations agrees to come to the aid of any other member if that nation is attacked. The combined strength of the group discourages attacks. Such groups include the North Atlantic Treaty Organization (NATO).

Improvement of international communication and trade increases understanding among nations. It reduces the danger of war by lowering the cultural and economic barriers that divide countries. Many European nations work together in a group called the European Union. This organization works to improve the flow of goods, ideas, and people from nation to nation and to achieve greater economic and political cooperation among its members. Robert J. Art

Peace Bridge is a symbol of the years of friendship between the peoples of the United States and Canada. It extends 5,800 feet (1,768 meters) across the Niagara River from Fort Potter, in Buffalo, New York, to Fort Erie, Ontario. A company with 9 Canadian and 16 American directors owns the steel bridge. Peace Corps is an overseas volunteer program of the United States government. Men and women in the Peace Corps work with people in developing countries to help them improve their living conditions. The chief goals of the corps are (1) to help the poor obtain everyday needs, (2) to promote world peace, and (3) to increase understanding between Americans and the people of other nations.

The Peace Corps was established in 1961. In 1971, it became part of ACTION, a government agency that combined several volunteer programs. In 1981, the Peace Corps became an independent agency. In 2002, it became part of the USA Freedom Corps, an umbrella group for several national service organizations.

How the corps works. The Peace Corps selects, trains, and supports American men and women for two years of service. It sends people into a country only at the request of that nation. Corps members are called *volunteers,* and the country in which they serve is called the *host country.* The Peace Corps consults the government of the host country in deciding what projects to undertake and what skills to seek when choosing volunteers. Most projects are designed to raise the living standards of people who live in villages. The corps works to improve agriculture, health care, and educa-

tion in the host country. It also promotes local leadership and local management of community resources and helps develop small businesses.

Volunteers serve in Africa, Asia, Eastern Europe, and Latin America and on various islands in the Pacific Ocean. They live and work with people of the host country. The most important part of their work consists of training the people to do the job that the volunteers are doing. For example, a Peace Corps carpenter may teach people construction skills as he or she works.

The Peace Corps cooperates with volunteer organizations of other countries and with the United Nations Volunteer Program. The corps also works with various private organizations in the United States. For example, the Peace Corps Partnership Program works with American schools, civic organizations, youth groups, and other private organizations. Under this program, the corps arranges for the construction of a clinic, school, or other community facility in the host country. The project is then financed by the participating organization.

Choosing volunteers. To qualify for service in the Peace Corps, a person must be a U.S. citizen and at least 18 years old. The corps has no upper age limit. Married couples may volunteer if both the husband and wife have skills the corps can use in the same country.

The Peace Corps seeks dedicated individuals who can learn skills and work effectively with people. Volunteers must be able to adapt to cultures and living conditions widely different from those in the United States. Members of the corps vary greatly in abilities and background. Most are college graduates, but the corps does not require applicants to have college training. Applicants who have experience in agriculture, medicine, and certain other fields receive special consideration.

All applicants for service with the Peace Corps fill out a detailed application form. They list their educational and work background, skills, special interests, and hobbies. Applications may be obtained by writing to the Peace Corps, Washington, DC 20526. In choosing volunteers, the corps uses the information on the application form, together with references from the applicant's employers, friends, and teachers.

Volunteers receive from 8 to 14 weeks of training. Most of them train in the host country, but some attend a Peace Corps training center in the United States. Trainees study the culture, history, and language of the country in which they will serve. They also receive technical training for their specific assignments.

Members of the Peace Corps receive an allowance for living costs and are provided with housing, medical care, and transportation. After returning to the United States, they receive a readjustment allowance of $200 for each month of service.

History. The idea of an "army" to work for peace was first suggested by the American philosopher William James in 1904. James made the proposal in a speech in Boston and, in 1910, developed the idea more fully in a pamphlet. He suggested forming a youth peace army to handle important but dangerous civilian projects.

After World War II ended in 1945, many private groups set up international work camps. Others sent young Americans to share their skills with students and workers in other countries. These groups followed the example of the American Friends Service Committee, a Quaker organization, which started its first international projects in 1917.

In January 1960, Senator Richard L Neuberger of Oregon and Congressman Henry S. Reuss of Wisconsin asked Congress to study the possibilities of a youth corps program. Later that year, Senator Hubert H. Humphrey of Minnesota proposed that Congress create a peace corps. Then, Senator John F. Kennedy of Massachusetts used the proposal for a peace corps in his 1960 presidential election campaign. Kennedy declared: "There is not enough money in all America to relieve the misery of the underdeveloped world in a giant and end-

Kennedy was elected president in November 1960, nd he established the Peace Corps on March 1, 1961. he first volunteers started training at Rutgers University New Brunswick, New Jersey, that same year. Sargent hriver was the first director of the Peace Corps.

Many thousands of Americans have served as Peace orps volunteers in dozens of countries. The United tates also supported the efforts of other nations to set p similar organizations.

Service programs in other countries. Agencies milar to the Peace Corps have been set up by Ausalia, Austria, Belgium, Canada, Denmark, Finland, rance, Israel, Japan, Korea, Liechtenstein, the Netherınds, New Zealand, Norway, the Philippines, Sweden, aiwan, and the United Kingdom. These organizations ary in several ways, including name, size, and length of ervice. But all of them, like the Peace Corps, enlist volnteers from among their citizens to serve in other ountries.

Several nations also have national volunteer corps at work within their own countries. In some cases, embers of these organizations work with Peace Corps ersonnel. Critically reviewed by the Peace Corps

eace pipe, also called *calumet, KAL yuh meht,* was a eremonial tobacco pipe that North American Indians smoked as a sign of peace and friendship. They passed it from one person to another. Among the Indians of the Great Lakes, Mississippi Valley, and Great Plains, this pipe had a stone bowl and a long wooden stem elaborately decorated with feathers. Early French explorers called the pipe and the dance held in its honor the *calumet,* from their word for the reed that sometimes formed the stem of the pipe. Most Indian pipes were not peace pipes. Indians of many tribes smoked solely for pleasure. Other pipes were used only in religious ceremonies. W. Roger Buffalohead

Peace River, in western Canada, is the largest tributary of the Mackenzie River. It is 945 miles (1,520 kilometers) long, including the length of its main branch, the Finlay. It drains the Peace River district, a fertile farming area in northwestern Alberta and eastern British Columbia. For location, see **Alberta** (physical map).

The Peace River is formed where the Finlay and Parsnip rivers join in central British Columbia. It cuts through the Rocky Mountains and flows in a general easterly direction for about 300 miles (480 kilometers). At the town of Peace River in Alberta, where the Smoky River joins it, the river turns and flows north through steep sandstone cliffs. The riverbed then gradually widens and becomes more shallow until the stream enters the Slave River 815 miles (1,310 kilometers) from its source at Finlay Forks.

Williston Lake, formed by the W.A.C. Bennett Dam across the Peace River, is the largest body of fresh water in British Columbia. It covers 680 square miles (1,761 square kilometers).

During the early fur trade, the Peace River was part of a major freight route. A railway built from Edmonton, Alberta, after World War I (1914-1918) opened the Peace River district. Grande Prairie, Alberta, is now the center of this area. Some of the world's finest hard northern wheat comes from the Peace River district. This district

is the northernmost commercial crop-producing area in North America.

Vast pools of oil and natural gas lie beneath the Peace River district. Pipelines transport these minerals to Edmonton, and on to Vancouver, B.C. Natural gas refined at Taylor Flats is sent through a 650-mile (1,050-kilometer) pipeline to southern British Columbia and the United States. G. Peter Kershaw

Peach is a roundish, yellow to reddish, edible fruit. It has a hard, deeply pitted stone. Its flesh may be soft or quite firm. Among *deciduous* (leaf-shedding) tree fruits, only the apple and the pear are more widely distributed throughout the world than the peach. Peach trees grow in most temperate regions.

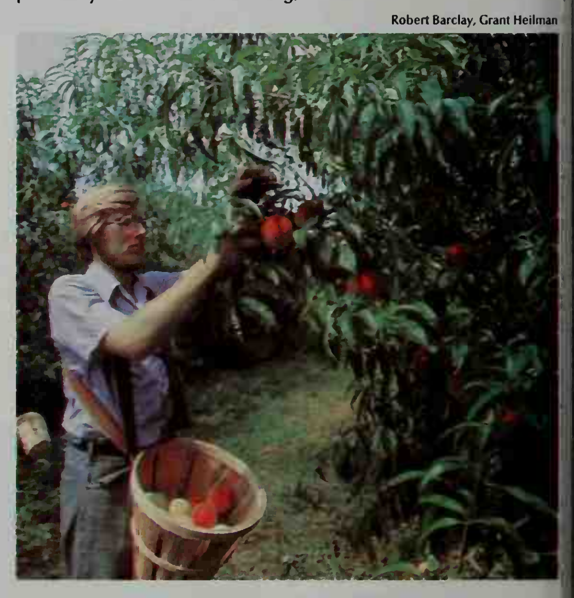
Horticulturists (plant scientists) believe that China is the native home of the peach. They believe the trees grew there at least 4,000 years ago. The peach was spread throughout Europe by the Romans. Spanish explorers brought the peach to the Americas as early as the 1500's, and English colonists also brought peaches in the 1600's. The United States is the world's leading producer of peaches. Many peach trees are planted in commercial orchards, and some are cultivated in gardens as ornamentals.

Peach trees grow 15 to 25 feet (4.6 to 7.6 meters) high. Their slender leaves have toothed edges. Flowers appear before the leaves. The delicate pink blossoms may be large and showy, but sometimes are quite small. They appear early in the spring and can be injured by late frosts. Most commercial peach orchards are located in regions where there are few late frosts. Clear, hot weather during the growing season is best for peaches. They are grown southward from the Great Lakes region of the Midwest into the Deep South, and along the Atlantic and Pacific coasts.

Cultivars. There are many *cultivars* (varieties produced by selective breeding) of peaches. They ripen from early summer to fall—some as late as October. Peaches are called *freestone* or *clingstone,* according to how difficult it is to remove the pit from the fruit. The fruit of freestone peaches is usually softer than that of clingstones. But some cultivars of clingstones are very mellow, with fine aroma and excellent texture.

Perhaps the best-known peach cultivar is Elberta, a freestone. It originated in 1870 in Marshallville, Ga. Other well-known freestone cultivars are J. H. Hale, Redhaven, Hiley, Halehaven, July Elberta, and Golden Jubilee. Important clingstone cultivars include Fortuna, Paloro, Johnson, Gaume, and Sims. Nectarines are similar to peaches. The two fruits are essentially alike except for the skins, and the trees are identical (see **Nectarine**).

Growing peach trees. Most commercially important cultivars of peach are reproduced by attaching a bud of the desired cultivar to a rootstock from a different cultivar. This procedure is called *budding.* Rootstock cultivars are chosen on the basis of their ability to produce stronger or dwarf-type trees. One-year-old rootstocks are budded in late summer. The newly budded trees lie dormant until the next spring, when the buds are forced into growth. The age of a peach tree is determined by the age of the bud even though the rootstock is one year older.



Cultivation. Peach trees grow best on a deep, well-drained, medium-textured soil, such as a sandy loam.

Growers plant standard-sized trees 18 to 25 feet (5.5 to 7.6 meters) apart in the orchard. But those trees grown on dwarfing rootstocks are planted 12 to 15 feet (3.7 to 4.6 meters) apart. A peach orchard begins to bear large crops about 3 or 4 years after it is planted. If the trees are healthy, they live about 20 years. They reach peak production when they are 8 to 12 years old. A single tree may produce from 4 to 10 bushels (87 to 220 kilograms) of peaches.

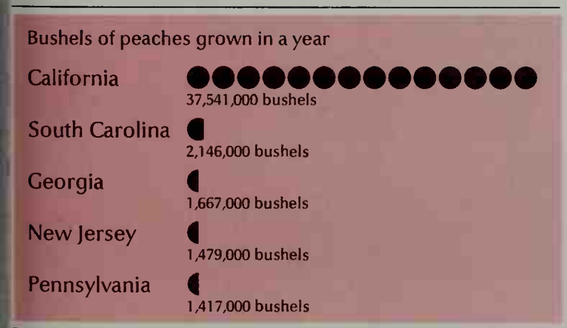
Peach trees must be watered regularly. The amount of water required varies with climate, soil texture and depth, and depth of the root system. Enough water must be used to wet the entire root system. Cultivation of the orchard is necessary to destroy weeds, which compete with the trees for water and mineral nutrients in the soil. Chemical sprays are often used to control weeds.

Peach trees need various mineral nutrients for normal

growth. Most of these occur in sufficient quantity in the soil. But usually nitrogen must be added. Special fertilizers are used to supply this element.

Pruning is essential for good fruit production. Peach trees are pruned more heavily than most other fruit trees. Trees are pruned low to make spraying and picking easier. Because the fruit is produced on shoots of the previous season's growth, about a third of the last year's growth is kept. All the rest is cut off. The trees produce so many peaches that the fruit must be thinned. Growers remove some peaches early in the season. This technique increases the size and improves the quality of the fruit that remains. Tree-ripened peaches have the best flavor. They are harvested when ripe but still firm.

Uses. Fresh peaches are eaten as a delicacy. But many of the fruits are canned, principally those of the clingstone cultivars. Some peaches are frozen for commercial use, and a few of the fruits are dried. Pastries and preserves can be made from peaches. Distillers sometimes make brandy from them.



Diseases. A number of diseases attack the peach. *Brown rot,* a fungus, causes serious damage. It rots the fruit and prevents the flowers from opening. *Peach leaf curl* is very troublesome. To prevent this disease, growers spray the tree early in spring before the leaves emerge. Other fungi cause *mildew, rust,* and *blight.* Sprays of organic chemical fungicides are used to control these diseases.

Peach trees are susceptible to many virus diseases. Among the serious ones are *peach yellows, X-disease, Western X-disease, ring spot,* and *peach mosaic.* Trees infected with these diseases must be uprooted.

Insects. Several insects damage peach trees. The *peach twig borer,* the larva of a moth, may bore into the fruit. But usually it bores into the trunk and branches, sometimes killing the tree. The peach moth larva destroys twigs and fruit. Many other moth larvae and beetles prey on the foliage, as do several kinds of caterpillars. Organic chemical insecticide sprays are used to control insects. Some chemicals for disease and insect sprays may be combined.

Production. Peaches are grown throughout the world. The leading peach-growing countries are, in order of production, China, the United States, Italy, and Greece. About three-fourths of the peaches grown in the United States come from California. Clingstone cultivars make up about two-thirds of California's peach crop. California's rate of production varies little, but

emerge when peaches are blooming. They lay eggs on leaves, and the eggs hatch into larvae. From 4 to 7 generations of larvae appear yearly. The first generation eats tender twigs. Later generations of peach moth larvae feed upon the fruit.

The peach moth also attacks apples, pears, quinces, cherries, and plums. Parasitic wasps and flies, including some imported from abroad, provide aid in controlling the moth. A synthetic *pheromone* is sometimes sprayed on peach orchards to keep peach moths from mating (see **Pheromone**). Insecticide sprays may be needed to control large numbers of the moths. John R. Peacock, also called *peafowl,* is one of the showiest of all birds because of its great size and the beauty of its feathers. Technically, the word *peacock* refers only to the male peafowl. The female bird is called a *peahen.* However, most people use the term *peacock* for either sex.

The Indian peafowl is the best-known species. The male is about as large as a turkey. It has a metallic greenish-blue neck and breast, purplish-blue underparts, and a long train of greenish feathers brilliantly marked with bold spots that look like eyes. These feathers grow from the back and not the tail. During courtship, the male bird spreads the train into a gorgeous fan as he parades slowly in front of the female. The female bird is smaller and less vividly colored than the male bird. The female bird has no train.

Indian peafowls live wild in India and Sri Lanka, and can be seen in city parks and on country estates. The dark-green, broken coloration may have protective

value in the midst of colorful tropical foliage. These birds eat snails, frogs, and insects, as well as grain, juicy grasses, and bulbs. They often destroy crops. Varieties with white plumage are sometimes found in captivity. The green "jungle" peafowl, found in Burma, Malaysia, and Java, has a golden-green neck and breast.

Tame peacocks may be found in all parts of the world. The young cannot stand the changeable weather of temperate climates very well, and are hard to raise. The hen makes its nest in a protected spot on the ground. It lays 10 or more brownish eggs.

In ancient times, the peacock was carried to all parts of the world as a great treasure. During the reign of Solomon, "once in three years came the navy of Tharshish, bringing gold and silver, ivory, and apes, and peacocks" (I Kings 10: 22). The peacock is mentioned in *The Birds,* a play by Aristophanes, written in Greece during the 400's B.C. Pliny speaks of it as common in his day in Rome, where the peacock was considered a great delicacy as a roast, served in its own feathers.

Scientific classification. Peacocks belong to the family Phasianidae. The Indian peafowl is *Pavo cristatus.* The green peafowl is *P. muticus.* John W. Fitzpatrick

Peale was a family of famous American artists. At least 20 members of the family, covering three generations, were artists. Charles Willson Peale (1741-1827), the enthusiastic family patriarch, believed that anyone could learn to draw. He taught many of his 17 children and also his brother James Peale (1749-1831). James in turn taught five of his children. James painted portraits, figure compositions, landscapes, and still lifes. They were done with the directness and charm that mark the best work of the family.

Raphaelle Peale (1774-1825) and Rembrandt Peale (1778-1860) are the best known of Charles Willson Peale's artist sons. Raphaelle is noted for his still lifes and miniatures. Rembrandt painted hundreds of portraits. Sarah Miriam Peale (1800-1885), a daughter of

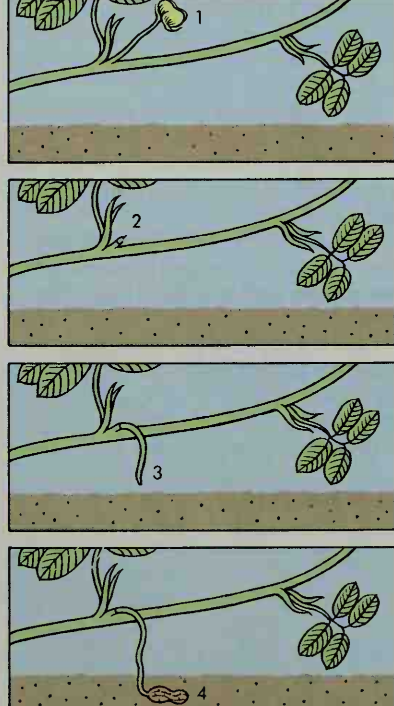
eanut is a plant species grown mainly for its fruit. The
eanut is a *legume*—that is, it bears fruit in the form of
ods (shells) that contain one or more seeds. The peanut
more closely related to peas than to nuts. There are
vo seeds in most peanut pods. These tasty seeds are
also called peanuts. They are a favorite food, whether eaten alone or mixed into candy, cookies, or pies. Peanut butter is also a popular food. Worldwide, peanuts are grown chiefly for oil.

The peanut plant is unusual because its pods develop underground. For this reason, peanuts are often called *groundnuts.* Other names for peanuts include *arachides, goobers, mani,* and *pinders.*

Peanuts are an important crop, especially in the warm regions of the world. Farmers in Africa and Asia grow about 90 percent of the world's peanuts. The leading peanut-growing countries are China, India, Indonesia, Nigeria, and the United States. Georgia produces more peanuts than any other U.S. state—about 40 percent of the country's annual peanut crop.



Peanuts are a nutritious food. There are more energy-giving calories in roasted peanuts or peanut butter than in an equal weight of beefsteak.

Uses of peanuts

As food. Manufacturers roast peanuts inside the pods and sell them as whole *roasted-in-shell* peanuts. In addition, they remove the shells and roast and sell only the seeds. Manufacturers usually salt peanuts to improve their flavor.

Manufacturers make *peanut butter* by roasting and *blanching* (removing the skins or seed coats from) the peanuts, and then grinding them into a thick paste. Pea-

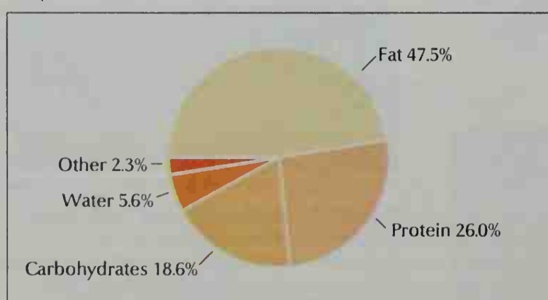
nut butter is eaten alone and in sandwiches. About half of the peanuts consumed in the United States are eaten as peanut butter. About a fourth are sold as roasted peanuts.

Roasted peanuts are eaten alone or mixed into candies, cookies, pies, and other bakery products. Some ice cream is flavored with peanut butter. *Peanut bread* is made from ground peanuts. Peanut bread is rich in proteins and low in starch. Peanuts are sometimes sold fresh as *boiled peanuts.* Instead of drying the peanuts after picking, farmers wash the peanuts and boil them in salt water.

Peanut seeds consist of almost 50 percent oil. Peanut oil is used to fry foods. It smokes only at high temperatures and does not absorb odors easily. Many salad oils and dressings, margarine, and other vegetable shortenings also contain peanut oil.

In industry. Low grades of peanut oil are used as an ingredient in soaps, face powders, shaving creams, shampoos, and paints. They are also used in making *nitroglycerin,* an explosive. Peanut oil has also been tested as an alternative fuel source.



The solid that remains after the oil is removed from peanuts is a high-protein livestock feed. Peanut protein can also be used to make a textile fiber that is called *Ardil.*

Even the shells of peanuts have uses. Manufacturers grind the peanut shells into powder. This powder is an ingredient in plastics, cork substitutes, wallboard, and abrasives.

On farms. Peanut foliage makes good hay. But most

farmers return the harvested plants to the ground to fertilize the soil.

Growing peanuts

The peanut is grown as an annual crop. It can grow up to 2 $\frac{1}{2}$ feet (75 centimeters) high and from 3 to 4 feet (90 to 120 centimeters) across. Peanut plants range in type from *bunch* plants to *runner* plants. Bunch plants grow upright. Runner plants spread out on or near the ground as they grow. Growers group peanuts into four market types: (1) large-seeded Virginias; (2) smaller-seeded Virginias, called *runners;* (3) Spanish; and (4) Valencia. Both kinds of Virginias include bunch and runner plants. Spanish and Valencia types are bunch.

Peanut plants bear many small, yellow, pealike flowers where the leaves are attached to the stems. The plants blossom continuously for two to three months. Flower buds open at sunrise. Fertilization takes place during the morning, and the flowers usually wither and die about noon. Within a few days, the *pegs* (stalklike stems of the pods) begin to grow. They grow slowly at first, but gradually grow more rapidly.

The pegs grow downward and push into the soil to a depth of 1 to 3 inches (2.5 to 8 centimeters). The grown pegs may be about 7 inches (18 centimeters) long. The tips of the pegs contain the developing seeds. They swell and mature into peanut pods. Most pods contain two seeds, but some may contain only one or as many as five seeds.

Cultivation. Peanut plants grow best in light, well-drained, sandy soil. They need much sunshine, warm temperatures, moderate rainfall, and a frost-free growing period of four or five months.

Farmers prepare the soil by plowing it deeply and thoroughly. Loose soil is important so that the pegs can penetrate the soil easily. Farmers plant peanut seeds 2 to 3 inches (5 to 8 centimeters) deep at intervals of 3 to 6 inches (8 to 15 centimeters), and in rows 24 to 36 inches (60 to 90 centimeters) apart.

Farmers must harvest peanuts at exactly the right time. If they harvest their peanut crops too early, many of the pods will not have ripened. If they harvest their crops too late, the pegs may snap, and many of the pods will be left in the soil. Most of the pods ripen 120 to 150 days after planting.

At harvest time, farmers use mechanized diggers to slice through the *tap* (main) root of each plant below soil level. The plants, with pods attached, are dug from the soil and turned upside down to dry in the sun. Special machines called *peanut combines* remove the pods from the sun-dried plants. The pods are further dried artificially in wagons. The pods are cleaned and graded before they are shelled for processing.

Processing peanuts

Most shelled peanuts are either *oil roasted* or *dry roasted.* Oil roasting is the more widely used method. In this process, manufacturers blanch the peanuts and fry them in oil. Dry-roasted peanuts are glazed with oil, sprinkled with salt, and roasted in large ovens.

Over 60 percent of the world's peanut production is used to produce oil. Some processors use a chemical *solvent* to dissolve oil from the peanuts. The oil is recovered from the solution by evaporation. In another

nethod, peanuts are ground and pressed in large tube-
haped grinders. The oil is collected, filtered, and de-
dorized. The *peanut meal* left over after the oil is ex-
racted is sometimes ground into peanut flour. In some
ountries, people eat peanut meal as a high-protein
neat substitute.

History

Peanuts are native to South America. South American
ndians were growing peanuts at least 1,000 years ago.
arly North American settlers grew peanuts, but no one
nows whether peanuts were cultivated in North Ameri-
a before the settlers arrived. Early colonists fed peanuts
) hogs. Peanut growing increased rapidly during and
fter the American Civil War. But peanuts did not be-
ome an important commercial crop until about 1917.

George Washington Carver made an extensive study
f peanuts. Carver is credited with having found more
nan 300 uses for the plant and its fruit. See **Carver,
eorge Washington.**

Since the 1930's, peanut yields in the United States
ave increased dramatically. In Georgia, for example, the
verage yield per unit of peanut farmland is about five
mes greater today than it was in the 1930's.

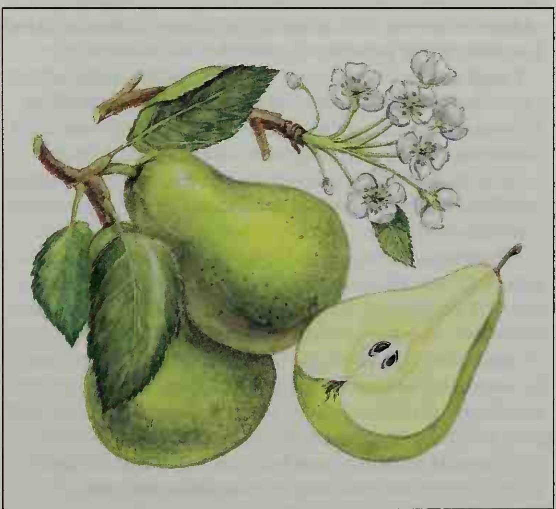
ear is a fleshy fruit. Some pears are large and round at
ne blossom end and taper inward toward the stem.
)thers may be almost completely round, like an apple,
r as small as a cherry. The pear tree is closely related to
ne apple and the quince. It grows in temperate regions
nroughout the world. The *common,* or *European,* pear
native to southern Europe and Asia. The *Japanese* and
hinese pears, often called *oriental* pears, are descend-
d from the wild *sand* pear of central and western Chi-
a. There are many hundreds of pear varieties.

The fruit is covered with a smooth, thin skin, which
nay be yellow, russet, or red. Its juicy flesh is sweet and
ellow. It is also tender, though tiny, hard grit cells
nake the flesh of some pears taste sandy. European
ears contain only a few of these cells. But other pears
nay have large numbers of them. Enclosed in the center of the fleshy portion is a core much like the core of an apple. This core may contain as many as 10 seeds.

The common pear tree may grow 45 feet (14 meters) high and be 25 feet (8 meters) wide. It sometimes lives to be quite old, often more than 75 years. Its leaves are almost oval but have a sharply pointed tip. They usually have toothed edges and prominent veins. The white flowers grow in clusters of 4 to 12 blossoms.

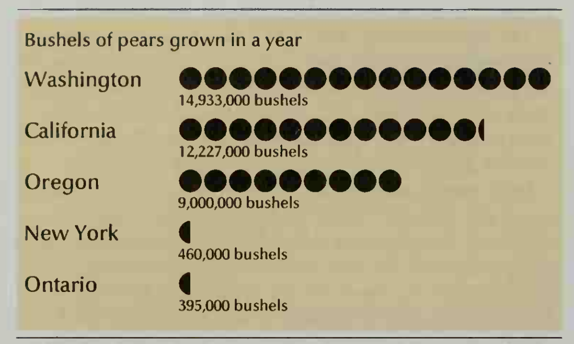


How pears are grown. Pears, like most other fruit trees, are grown by grafting the desired variety on a rootstock. Seedlings of European pears are usually used for rootstocks. They are called French pear seedlings, even though the seeds are no longer imported from France. Growers obtain most of the seed used for these seedlings from pear canneries. The seeds are usually from Bartlett pears.

Quince rootstock is used to produce dwarf pear trees. But some European pear varieties will not grow on quince. Then the grower uses an intermediate stock. To do this, the grower first grafts the intermediate stock, which will grow on the quince. When the intermediate stock shoots are long enough, the European variety wanted is grafted to the shoot. Then the grower cuts off all side growth except that on the last graft.

Growers plant standard-sized trees about 18 to 25 feet (5 to 8 meters) apart. They plant dwarf trees about 10 to 15 feet (3 to 4.6 meters) apart. Pear trees grow well in soils heavier and wetter than those in which peach trees will grow. Sometimes fertilizers are added to the soil to increase the tree's growth. In some regions, certain varieties may not need cross-pollination to bear fruit. But in other regions, the same varieties may need to be cross-pollinated. Some varieties always need cross-pollination.

Growers prune pear trees as they do some other orchard fruit trees. They cut off unnecessary branches so light can reach all parts of the tree. They also keep the tree quite low to make it easier to spray and pick fruit.



Some pear trees seem able to withstand very cold weather. Therefore, certain varieties can be grown in regions with severe winters. However, many pears thrive

in hot, dry areas. These varieties are grown in many Pacific Coast States of the United States. Hybrids produced from common and Japanese pears are quite hardy.

Varieties. From the common, or European, pear have come such familiar varieties as Bartlett, Comice, Anjou, Bosc, Hardy, Seckel, and Winter Nelis. Because of the gritty nature of the fruit of some older varieties, which is objectionable to many people, oriental pears were crossed with the common pear. From this cross-breeding come the varieties Kieffer, LeConte, and Garber. But some extremely fine varieties of oriental pears have become available and are grown in the Pacific Coast States.

Bartlett pears ripen in summer, but most other varieties ripen later, usually in early fall. Oriental pears ripen well on the tree. Other pears ripen to perfection only when they are removed from the tree. Therefore, these pears are picked while they are still green and hard. The fruit will ripen in a cool place where the temperature does not exceed 75 °F (24 °C). Many varieties, such as Winter Nelis and Forelle, can be kept in cold storage all winter. Temperatures range between 32 °F (0 °C) and 40 °F (4 °C). Most other pears, such as Comice and Anjou, must be removed from storage by midwinter.

Uses. Pears are used widely as a dessert fruit. About half of all pears grown are eaten fresh. But many are canned alone or with other fruits. Some pears are dried. Europeans use pears for pear cider, called *perry.*

Food value. Fresh pears contain about 14 percent carbohydrates and a small amount of protein and fats. They also contain calcium, phosphorus, iron, vitamin A, thiamine, riboflavin, niacin, and ascorbic acid. Pears have as many calories as apples, but more calories than peaches. Pears have fewer calories than either plums or cherries.

Diseases. Perhaps the greatest limiting factor in growing the common pear is the occurrence of fire blight. This disease is often called *pear blight* because pears are so susceptible to it. Fire blight is a destructive disease that spreads rapidly in warm, humid weather. It is caused by bacteria that attack blossoms, young twigs, and branches, killing them and turning them black, as if they had been burned by fire. The bacteria live from year to year in cankers on the tree trunk and limbs. Insects carry them from tree to tree. Rain, dripping through the tree, carries them from branch to branch. Contaminated pruning tools also spread the disease. Growers prune away all the diseased parts as soon as they are noticed. The growers also spray the tree with a copper solution, or with solutions containing antibiotics such as terramycin and streptomycin. Other damaging diseases include false fire blight, leaf spot, pear decline, powdery mildew, scab, and collar rot.

Insects. The codling moth is a serious pest. It causes wormy fruit. Pear psylla affects the skin of the fruit and the tree's foliage. Pear-leaf blister mite and various other mites cause brownish blisters on the undersides of the leaves. They also cause the fruit to be small and to fall. Pear thrips attack the buds early in spring, causing them to shrivel and turn brown. Other pests include aphids, leaf rollers, lygus bugs, midges, oriental fruit moths, scale insects, slugs, and stink bugs.

Production. The leading pear-growing countries are, in order of production, China, Italy, and the United States. About 95 percent of the annual U.S. pear crop comes from the Pacific Coast States of California, Oregon, and Washington. Bartlett pears make up about 60 percent of the total U.S. crop. Ontario and British Columbia are the leading pear-growing provinces of Canada.

History. No one knows when pears were first found. The Greek poet Homer, who may have lived during the 700's B.C., mentioned this fruit in his works. So did the Roman playwright Publilius Syrus.

The pear has been grown in America since the earliest colonists arrived. In 1630, John Endecott (or Endicott) of Massachusetts is supposed to have planted the *Endicott pear,* which is famous in the history of horticulture. Most pears in colonial America came from France, then the center of European pear growing. One of the largest pear trees in the world once grew in the Mississippi Valley, near the French settlement of Cahokia. Pear growing spread throughout the United States. Pears are grown in gardens and farms in almost every state. However, the pear has never become as popular as the apple.
Fenton E. Larsen

Scientific classification. The pear tree belongs to the rose family, Rosaceae. The common, or European, pear is *Pyrus communis.* Most oriental pears are *P. pyrifolia.* Others are the Ussurian pear, *P. ussuriensis,* and the Callery pear, *P. calleryana.*

Pearl is one of the most valuable gems. Large, perfectly shaped pearls rank in value with the most precious stones. But pearls are different from other gems. Most gems are minerals mined from beneath the earth. But pearls are formed inside the shells of oysters. Mineral gems are hard and usually reflect light. However, pearls are rather soft, and they absorb, as well as reflect, light.

How pearls are formed

Oysters and other shell-forming mollusks make a special substance, called *nacre* (pronounced *NAY kur),* that lines the insides of their shells. This smooth lining is called the *nacreous layer,* or *pearly layer,* and it is often lustrous. It is formed by cells from a fleshy body organ called the *mantle.* When a foreign substance, such as a bit of shell or a tiny parasite, enters the mollusk's body, the mantle cells begin to work. They cover the invading substance with thin sheets of nacre. They build successive circular layers of nacre until the foreign body is enclosed in the shell-like substance, forming the pearl.

The pearl has the same luster and color as the lining of the shell of the mollusk. But few pearl-forming mol-

lusks produce the beautifully colored nacre that is essential for valuable pearls. Valuable pearls come from some species of oysters and other mollusks that live in tropical seas. Some species of mussels found in rivers also produce precious pearls. Edible clams and oysters have dull shells, so their pearls are without luster. As a result, they have no value as gems.

Characteristics of pearls

When a pearl is cut in two and examined under a microscope, the layers can be seen. Because the layers are *concentric* (formed in a complete circle around the central substance), the cut pearl looks like a sliced onion. The layers are made up of little crystals of a mineral substance called *aragonite,* a form of calcium carbonate. They are held in position by a cartilagelike material known as *conchiolin* (pronounced *kahng KY oh lin*). The tiny mineral crystals overlap and break up any light that falls on them into little rainbows of color. This gives pearls their iridescence, which jewelers call *orient.*

Conches, clams, and most edible oysters usually do not make pretty pearls because their aragonite crystals are too large. Even though the pearls may be of beautiful pink, white, or purple color, they lack iridescence.

Color. Oriental pearls, so called not because they come from the Far East but because they are iridescent, may also have color. These pearls may be "black," pink, orange, gold, cream, or white. "Black" pearls are really a dark gray. They are among the most valuable pearls.

Shape of a pearl is as important as its color. Round pearls, suitable for necklaces, are the most valuable. Next are button-shaped and drop-shaped pearls. These are often used for earrings. Matched pairs of these pearls are even more valuable than pairs of unmatched single ones. Pearls with irregular shapes are called *baroques.* They are less valuable than the others. Pearls made by a kind of snail called the *abalone* have wonderful color and luster but are almost never symmetrical.

Blemishes. Perfect pearls and pearls with only one blemish are the most valuable. Sometimes blemishes can be removed if the flaw is not too deep. Specially trained workers called *peelers* carefully scrape away the blemished layers. When they have removed the flaw, the pearl is smaller, but perfect. Such a pearl is worth more than the original large, but blemished, pearl.

Matching pearls. The matching of pearls to make a pair or a string makes the finished piece more expensive than the total cost of the individual pearls. Each added pearl must be like all the others in color and orient. Often it must be of the same size as the others. It must have no more than one tiny blemish. One blemish is acceptable because the pearl can be drilled for mounting at the blemish. Before people began to produce cultured pearls, it could take many years to fill a necklace of matched pearls.

Value. The cost of pearls sold in large quantities is determined by their weight. In a piece of jewelry, the value of a pearl is determined by its size, color, and luster. For example, matched pearls in a necklace cost more than the total of their individual values.

country of Bahrain. Other natural pearl-oyster beds were located in the South Pacific Ocean. Thousands of oysters had to be collected to produce even a small handful of pearls. For this reason, natural pearls were extraordinarily expensive. Today, few natural pearls are harvested for jewelry because the farming of cultured pearls produces pearls more cheaply.

Cultured pearls are real pearls made by oysters. They usually can be distinguished from natural ones only by tests made in laboratories. The cultured pearl has a larger central body around which the layers of nacre form. The cultured pearl also has fewer and thicker layers of nacre. Thicker layers of nacre increase the value of the pearl.

Cultured pearls were first produced by inserting in an oyster a bead made of *mother-of-pearl,* the nacre secreted by certain inedible clams and oysters (see **Mother-of-pearl**). A small amount of mantle tissue from another oyster also was inserted. The process was developed by Kokichi Mikimoto of Japan in the early 1900's. So successful was this process that the cultured-pearl business became much larger than the trade in natural pearls. Today, most cultured pearls are produced in Japan.

To produce cultured pearls, young oysters are planted in carefully selected oyster beds. When the oysters are 3 years old, they are taken from the beds to special

production plants. There, trained people open the oysters' shells and insert tiny pellets made of nacre or made from mussel shells. The workers then place the oysters in wire cages that will protect them from enemies. The cages are suspended from rafts and lowered into calm, protected waters near the shore.

Twice a year attendants raise the cages and remove seaweed and barnacles from the oysters. Progress of the oyster and the care given it are recorded on small metal tags attached to the cage. From one to three years after the pellets and tissue are inserted, the oyster is removed from the cage and its shell is opened. There is a valuable pearl in about 1 out of every 20 oysters opened. The pearl is washed, graded, and polished before it is sent to the market.

Imitation pearls are manufactured. Usually, manufacturers coat glass beads with a substance known as *pearl essence*. This substance, sometimes known by its French name *essence d'orient*, is a creamy liquid extracted from fish scales. Herring scales usually furnish the main ingredient. Imitation pearls can be recognized by the little loose flaps of dried pearl essence surrounding the hole. Often, a little of the glass bead that the pearl essence has failed to cover can be seen at this place on the pearl.

Care of pearls

Because pearls are soft, they are easily scratched by such hard gems as diamonds. Pearls should always be put away carefully, out of contact with other jewelry. Pearls contain an organic material, conchiolin. This material dries out in time, or it can be destroyed by high temperatures. The aragonite crystals that make up the layers of nacre dissolve very quickly in acid. Perspiration sometimes contains acid. Therefore, jewelry made of pearls should be washed and dried gently after it is worn. Richard J. Hoffmann

Pearl Harbor was the site of a surprise attack on the United States by Japanese military forces on Dec. 7, 1941. Japanese ships and airplanes attacked the United States naval base at Pearl Harbor on the island of Oahu in Hawaii. The attack caused heavy casualties and destroyed much of the American Pacific Fleet. The attack also brought the United States into World War II. "Remember Pearl Harbor" became the rallying cry for the country. American participation was a crucial reason why the embattled Allied nations, including the United Kingdom (U.K.) and Soviet Union, turned the tide and defeated the Axis nations, headed by Japan and Germany.

Background. Japan began a military expansion during the 1930's. It invaded China and much of Southeast Asia. Japan wanted to acquire the rich resources of Asia. The United States protested this aggression. It demanded that Japan stop its actions, but Japan ignored the demand. The United States then cut off exports to Japan. Japan had few natural resources, and it relied on exports of petroleum and other goods from the United States.

General Hideki Tojo became premier of Japan in October 1941. Tojo and other Japanese military leaders realized that only the United States Navy had the power to block Japan's expansion in Asia. They decided to try to cripple the U.S. Pacific Fleet at anchor in Pearl Harbor.

The attack. On December 7, the U.S. secretary of state conferred with two Japanese diplomats in Washington. While they talked, the Japanese military had already launched the attack on the U.S. facilities at Pearl Harbor. In the United States, the attack became known as the "Pearl Harbor sneak attack."

On December 7, Vice Admiral Chuichi Nagumo led a

33-ship Japanese striking force that steamed under the cover of darkness to about 230 miles (370 kilometers) north of Oahu. Early in the morning, his aircraft carriers launched 350 airplanes against the United States Fleet. The first bombs fell at about 7:55 a.m. The chief targets were 8 battleships among the 180 American vessels anchored in the harbor. The attack killed 2,388 people at Pearl Harbor and wounded about 2,000. It destroyed or damaged 21 American ships and more than 300 planes. The Japanese lost 29 aircraft.

On December 8, Roosevelt addressed Congress. He called December 7 "a date which will live in infamy." Congress declared war on Japan. In a radio speech the same day, Roosevelt urged Americans to back the war effort and avenge Pearl Harbor. He said, "Every single man, woman, and child is a partner in the most tremendous undertaking of our American history."

At the time of the attack, Nazi Germany had taken over much of Europe. The U.K. and the Soviet Union provided the main resistance to the Nazis. The United States had stayed out of the war. However, under the leadership of President Franklin D. Roosevelt, it provided extensive aid to Britain. Germany declared war on the United States on December 11.

Japan won many battles and gained much territory in the early days of U.S. participation in the war. However, a massive effort to produce equipment and supplies built American military strength, and the slogan "Remember Pearl Harbor" helped boost the morale of the population. The Allies gradually turned the tide against Japan and Germany. The long war, which had begun in 1939, ended in 1945 with the surrender of the Axis countries.

The war memorials. The ships destroyed in the Pearl Harbor attack include the U.S.S. *Arizona.* The battleship sits upright on the bottom of the harbor with more than 1,000 men entombed aboard. The U.S.S. *Arizona* Memorial, a roomlike structure, stands above the ship. The memorial is supported by pilings that reach the harbor bottom. About 1 $\frac{1}{2}$ million people visit the memorial each year. The names of those who died on the *Arizona* are carved in marble at one end of the room. Even today, bubbles of oil from the sunken *Arizona* rise to the water's surface. In 1999, the U.S. battleship *Missouri* was opened to the public, as the Battleship *Missouri* Memorial, in Pearl Harbor near the *Arizona.* This ship was the one on which the Japanese surrendered to the Allies, on Sept. 2, 1945.

Pearl Harbor as a naval base. In 1887, King Kalakaua of Hawaii gave the United States the right to develop a coaling station at Pearl Harbor. The harbor's name came from the pearl oysters that once grew in its waters. The United States made its first attempt to deepen the channel through the reef outside the harbor in 1902. The first dry dock was completed in 1919.

Pearl Harbor is now the site of the Pearl Harbor Naval Complex. It covers about 12,600 acres (5,100 hectares) on Oahu Island. Five major fleet commands in the Pacific have headquarters at the base. Paul W. Doerr

Lester B. Pearson

Prime Minister of Canada
1963-1968

Diefenbaker 1957-1963 | Pearson 1963-1968 | Trudeau 1968-1979

Philippe Halsm

Pearson, Lester Bowles (1897-1972), a former baseball and hockey player and university professor, served as prime minister of Canada from 1963 to 1968. He succeeded John G. Diefenbaker, whose Conservative government fell during a dispute between Canada and the United States. Diefenbaker had refused to allow atomic warheads on defense missiles provided by the United States. Pearson, a Liberal, believed that Canada had agreed to accept the warheads and should do so. Pearson resigned as prime minister in 1968. He was succeeded by Pierre Trudeau, the minister of justice in Pearson's Cabinet.

Long before taking office as prime minister, Pearson had won fame as an international statesman. He was the first Canadian to receive the Nobel Peace Prize. As Canada's secretary of state for external affairs, Pearson had helped establish the North Atlantic Treaty Organization (NATO), an alliance of Western nations. He also served on a United Nations commission that drew up cease-fire plans in the Korean War. Pearson then became president of the UN General Assembly. He later played a leading role in ending a war in Egypt over control of the Suez Canal.

At the UN and NATO, Pearson showed great ability at working behind the scenes to put ideas into action. He could work with people of any temperament. He eased many tense moments with a well-chosen remark. The public became familiar with Pearson's sporty bow ties and his nickname, "Mike." However, Pearson had a deep personal reserve that people found difficult to penetrate.

When Pearson became leader of the Liberal Party in 1958, one newspaper described him as "eloquent as a professor of algebra." Pearson admitted that he lacked the ability to inspire audiences with speeches. He spok with a slight lisp, which hurt his efforts to impress his listeners. He worked hard to make himself a better pub lic speaker, but did not enjoy making speeches.

"There are some things in politics I don't like, never have liked, and never will like," Pearson said. "The hoopla, the circus part of it, all that sort of thing. It still makes me blush."

Early life

Boyhood. Lester Bowles Pearson was born on April 23, 1897, in Newtonbrook (now part of Toronto), Ont. H was the son of Edwin Arthur Pearson, a Methodist min ister, and Annie Sarah Bowles Pearson. His father's father also had been a minister. Lester had an older brother, Marmaduke, and a younger brother, Vaughan Edwin Pearson had a great interest in sports, especiall baseball, and passed his enthusiasm on to Lester. The boy became a star athlete. He also was an excellent stu dent.

Education and war service. In 1913, Pearson entered the University of Toronto. He majored in history. World War I began in August 1914. The following March, at the age of 17, Pearson enlisted in the Canadian Army Medical Corps as a private. He completed h training in England and was sent to Thessaloniki, Greece, in 1915. He served in the Balkan area of southeastern Europe for a year and a half.

While Pearson was serving as a stretcher-bearer, some wounded British soldiers called the youth "Mike" because he looked Irish, and the nickname stayed with him. In 1917, Pearson received a lieutenant's commission in the infantry. That same year, he transferred to the British Royal Flying Corps as a pilot with the rank of flight lieutenant. Canada had no air corps at the time. Pearson returned to Canada in April 1918 because of injuries he suffered after being struck by a bus in London. He served for the rest of the war as a ground instructor at a Canadian base of the Royal Flying Corps.

After World War I ended in November 1918, Pearson returned to the University of Toronto. He graduated with honors in 1919. He then studied law for several weeks in Toronto. Next, Pearson took a job stuffing sausages in the Hamilton, Ontario, plant of Armour and Company, a meat-packing firm. During this period he played semiprofessional baseball. He then worked as a clerk in Armour's Chicago plant.

In 1921, Pearson received a scholarship from the Massey Foundation, which sent Canadians overseas to study. He studied history at Oxford University in England from 1921 to 1923. Pearson starred on Oxford's hockey team and played on the British Olympic team. He received a bachelor's degree and a master's degree from Oxford. From 1923 to 1928, he taught history as a lecturer and then as an assistant professor at the University of Toronto.

On Aug. 22, 1925, Pearson married Maryon Elspeth Moody (1902-1989) of Winnipeg, Manitoba. She had been one of his students at the university. The Pearsons had two children—Geoffrey Arthur Holland Pearson, who became a Canadian foreign service officer, and Patricia Lillian Pearson. Maryon Pearson disliked public life. But she was proud of her husband and anxious for his success, and she played an active role in his election campaigns. Pearson once declared: "I couldn't have carried on without her."

Public career

Early diplomatic service. A great turning point in Pearson's life came in 1928. He entered the diplomatic service during the administration of Liberal Prime Minister W. L. Mackenzie King, and served as a first secretary in the department of external affairs.

From 1930 to 1935, during the administration of Conservative Prime Minister R. B. Bennett, Pearson took part in several international conferences. Bennett particularly praised Pearson for his work on two Canadian economic commissions. Pearson received the Order of the British Empire, an award for public service from the British government.

King returned to power as prime minister in 1935. For six years, Pearson served as first secretary in the Canadian high commissioner's office in London. He returned to Ottawa in 1941 and for one year was assistant undersecretary of state for external affairs. In 1942, King assigned Pearson to the staff of the Canadian embassy in Washington, D.C.

In 1943, Pearson headed a United Nations commission on food and agriculture. This work led to the creation of the UN Food and Agriculture Organization in 1945. As chairman of another UN committee in 1943, he helped organize the UN Relief and Rehabilitation Administration (UNRRA). Pearson represented Canada at UNRRA meetings in 1944, 1945, and 1946. In January 1945, King appointed him Canadian ambassador to the United States. Pearson held this post until October 1946, when he returned to Ottawa as undersecretary of state for external affairs.

Pearson served as senior adviser of the Canadian delegation to the San Francisco conference that signed the United Nations Charter in June 1945. The Western nations favored him to be the first UN secretary-general, but the Soviet Union vetoed him.

Secretary of state for external affairs. In September 1948, Pearson was appointed secretary of state for external affairs of Canada. Canadian Cabinet members must be members of Parliament, so Pearson ran for a seat in the House of Commons the following month. The district of Algoma East in Ontario elected him to the House of Commons, and he won reelection in succeeding elections through the years. As Canada's secretary of state for external affairs, Pearson headed most of his country's delegations to the UN General Assembly from 1948 to 1956. King retired in November 1948, and Louis St. Laurent succeeded him as Liberal Party leader and prime minister.

In April 1949, Pearson represented Canada at ceremonies setting up NATO. He had been one of the principal architects of the alliance. Pearson emphasized that NATO, although it was established to ward off Communism, must also work for social, economic, and political progress. "Our treaty," Pearson declared, "is ... the point from which we start for yet one more attack on all those evil forces which block our way to justice and peace."

Pearson attended many other international conferences as part of his duties. He placed great importance on relations between developed countries, such as Canada, and less developed nations, such as India. He also worked to strengthen the nonmilitary aspects of NATO. In addition, Pearson tried to improve the UN. He served as president of the UN General Assembly in 1952 and 1953.

In October 1956, France, the United Kingdom, and Israel invaded Egypt, which had seized the Suez Canal. The UN accepted Pearson's proposal to set up an emergency military force to end the fighting and supervise a cease-fire. The UN troops quickly restored peace before the fighting could turn into a major war. On Oct. 14, 1957, Pearson became the first Canadian to receive the Nobel Peace Prize.

Liberal Party leader. In 1957, St. Laurent's government fell to the Conservatives, led by John G. Diefenbaker. After resigning as prime minister, St. Laurent also stepped down as Liberal Party leader. Pearson quickly decided to run for party leader. Although some Liberals considered him to be too inexperienced in domestic affairs, his fame as a statesman and his popularity in Parliament brought him victory in the race. The Liberal Party chose Pearson as its leader by a large majority in January 1958.

"No one ever started off worse than I did," Pearson said later. His advisers persuaded him to seek a parliamentary vote of no confidence in the new Conservative government. Pearson demanded that Prime Minister Diefenbaker return the government to the Liberals without an election. This demand gave Diefenbaker, a mas-

ter of parliamentary maneuvering, a chance to attack Pearson and the Liberals. Diefenbaker then dissolved Parliament and called an election in March 1958. Under Pearson, the Liberals went down to one of their worst defeats in history. They won only 49 of the 265 seats in the House of Commons.

After some initial discouragement, Pearson organized his tiny forces to mount an increasingly strong attack on the Diefenbaker government. While sharply criticizing the government in Parliament, Pearson and other Liberals also reorganized their party to give it a progressive and decisive image. These developments helped increase the popularity of the Liberal Party. In addition, the Diefenbaker government was handicapped by high unemployment in Canada.

As a result of Pearson's vigorous leadership, the Liberals doubled their parliamentary strength in the June 1962 elections. The Conservatives fell short of an absolute majority in Parliament, but they still had more seats than any other party.

Prime minister. Early in 1963, a dispute over defense policy strained relations between Canada and the United States. The question was whether Canada had agreed in 1959 to accept atomic warheads for missiles supplied by the United States. Pearson and the Liberals contended that Prime Minister Diefenbaker should accept the warheads, but Diefenbaker refused to do so. The Conservative government fell apart, with three ministers resigning, and was defeated by a vote of no confidence taken in February 1963.

In the elections of April 1963, the Liberals won 129 seats in the House of Commons, four short of an absolute majority. However, the small opposition parties promised to support Pearson. The Progressive Conservatives won only 95 seats, and Diefenbaker resigned.

Pearson became prime minister of Canada on April 22, 1963.

Pearson worked quickly to improve Canadian relations with Britain and the United States. He accepted nuclear warheads from the United States and took action to save a stalled treaty concerning the Columbia River. Pearson got along well with President John F. Kennedy of the United States, but he was less happy with Kennedy's successor, President Lyndon B. Johnson. The United States became increasingly involved in the Vietnam War during the mid-1960's. Pearson believed the war would end badly for U.S. foreign policy, and he urged the United States to seek a peaceful solution to the conflict.

Pearson faced serious domestic problems when he became prime minister. Disputes between French-speaking and English-speaking Canadians threatened national unity. Many French Canadians complained that they did not have equal opportunities and rights. One organization, the Quebec Liberation Front, demanded independence from Canada for the province of Quebec. This secret terrorist group used bombings and other forms of violence against the national government. Fortunately for Pearson, the Canadian economy boomed during the 1960's. This prosperity permitted his government to provide increased social services.

In 1965, Pearson called a national election because he wanted an absolute Liberal majority in the House of Commons. He kept control of the government, but the Liberals failed to win a majority.

In April 1968, at the age of 71, Pearson resigned as prime minister and as head of the Liberal Party. Pierre Trudeau succeeded Pearson. In August 1968, Pearson became head of a World Bank commission. The commission was set up to assist the economic progress of developing countries.

Pearson remained in good health until 1970, when he had an operation for cancer that resulted in the removal of an eye. He died of cancer at his home in the Ottawa suburb of Rockcliffe Park on Dec. 27, 1972. He was buried near Wakefield, Quebec. Robert Bothwell

As prime minister, Pearson met with President John F. Kennedy, *right,* in Hyannis Port, Massachusetts, and agreed to accept atomic warheads from the United States. This agreement helped ease the strain in relations between the two countries that had centered around this issue.

Peary, *PEER ee,* **Robert Edwin** (1856-1920), was an American Arctic explorer. Along with Matthew Henson, Peary is generally credited with the discovery of the North Pole in 1909.

Early life. Peary was born in Cresson, Pennsylvania, and raised in Maine. He graduated from Bowdoin College in 1877 and joined the United States Navy as a civil engineer in 1881. In 1886, the Navy assigned Peary to survey a canal route across Nicaragua. Peary hired Henson in 1887 as an assistant for this assignment.

Arctic expeditions. Early polar explorers had searched across the region for a Northwest Passage that would allow ships to sail between the Atlantic and Pacific oceans. But in Peary's time, explorers of several nations were competing to be the first to reach the North Pole. Each new record of "farthest north" achieved by explorers created international excitement. Peary was determined to win the race.

To reach the pole, explorers would have to overcome a number of obstacles. These difficulties included the bitterly cold temperatures, the hazards of a shifting ice pack, and impassable open channels of water called *leads* between drifting masses of ice. To have adequate supplies, explorers would have to haul *sledges* (heavy sleds) themselves or use dogs to help.

Peary began his first Arctic journey in the summer of 1886 to investigate the prospects for reaching the North Pole from northern Greenland. After only about three weeks, however, Peary was forced to turn back. In 1891, Peary led a major expedition to Greenland. The expedition included Henson; Peary's wife, Josephine; and his future rival Frederick A. Cook. The trip lasted 13 months. During it, Peary proved that Greenland is an island.

Peary and Henson made long dog sled trips over the polar icecap on several more expeditions (1893-1895, 1898-1902, and 1905-1906). By learning from the Inuit about proper dog handling, clothing, diet, and survival techniques, Peary became an expert Arctic traveler.

A number of wealthy Americans established the Peary Arctic Club to support Peary's expeditions. In 1904, the club commissioned a special ship, the *Theodore Roosevelt,* for his use. The *Roosevelt* sailed on Peary's 1905-1906 trip, during which the explorers achieved a new record for "farthest north" at 87°6' north latitude.

Bettmann Archive

Robert E. Peary won fame as a great Arctic explorer. This photograph shows him after he returned from an expedition in 1909. Peary is usually credited with having discovered the North Pole on the expedition.

"The Pole at last." Peary sailed to Cape Sheridan on Ellesmere Island in the Canadian Arctic in September 1908. He then established his supply base at Cape Columbia at the island's northern tip. Peary's main party left Cape Columbia on March 1, 1909. The group included 24 men, 19 sledges, and 133 dogs. They faced over 400 miles (640 kilometers) of broken and drifting ice to reach the pole. The group was delayed several times by having to wait for leads to freeze before they could continue. Several support teams helped Peary on the journey's early stages, then returned to base after leaving food at various points for the return trip. Robert A. Bartlett led the last support party and left Peary, Henson, and four Inuit about 140 miles (225 kilometers) from the pole.

With 40 dogs and five sleds, the men left on April 2 for the final assault on the pole. On April 6, Peary calculated that he had reached the North Pole. The explorers began their return journey the next day. They reached Cape Columbia on April 23, but ice prevented the *Roosevelt* from sailing south until July.

Dispute with Cook. Before Peary arrived back in the United States, he heard that Cook had claimed to have reached the pole from Greenland in 1908. Peary was outraged at Cook's challenge and claim of success. He doubted that Cook's experience and resources were adequate for a polar victory and quickly declared that Cook's claim was a fraud. Peary's supporters rallied to his cause and denounced Cook. Suspicions about Cook grew as he failed to submit adequate evidence to geographical societies. By 1910, Cook had been generally discredited, and Peary was recognized as winner of the polar race. Congress honored him with a promotion to rear admiral in 1911. After Peary died, he was buried at Arlington National Cemetery with full honors.

The controversy about the first journey to the North Pole continues. Over the years, a number of books have been written about Cook that portray him as the underdog of polar adventure who was wrongly treated by the public and the influential Peary Arctic Club. However, no further evidence has been found to support Cook's claim. Meanwhile, scientists and modern polar travelers have examined Peary's geographical evidence, and some of them have questioned his achievement. Most experts believe that Peary possibly gave himself the benefit of the doubt by claiming the pole, but that he, unlike Cook, was certainly close to it. William R. Hunt

Peasants' Revolt. See Wat Tyler's Rebellion.

Peasants' War refers to the rebellion of German peasants against their lords in 1524 and 1525. This was the greatest mass uprising in German history. The rebellion broke out late in 1524 at Stühlingen in the Black Forest and spread northward like wildfire. Soon all Germany, except Bavaria, felt its impact. The peasants stormed the castles and forced the nobles to grant their demands. Their flag, called the *Bundschuh,* was a black, white, and red cloth with a picture of a peasant's shoe.

The peasants had grumbled over the ever-increasing dues and services demanded by the princes for 50 years. The teachings of Martin Luther contributed to the peasants' rebellious feelings. The peasants hoped for and needed Luther's support of their uprising. However,

e rejected their charter of liberties. Luther urged the easants to lay down their arms. When the peasants did ot do what he suggested, Luther summoned the lords ı a pamphlet to strike down and stab the rebels "like ıad dogs." The nobility killed as many as 100,000 peasnts before the rebellion ended. The loss of so many eople eliminated the peasantry as a political factor for ıe next 300 years. William H. Maehl

'eat is partly decayed plant matter that has collected in wamps and marshes over long periods of time. It is enerally the first stage in the formation of coal. Dried eat varies from a light yellow-brown substance resembling tangled hay, to deeper layers of dark brown, comact material that looks like brown coal.

Peat forms in layers. The pale upper layers contain the emains of plants, herbs, and moss that died and rotted ı the shallow, acid water. They are compressed by the veight of water and other plants to form peat. The lower ıyers are about 90 per cent water, and look like mud.

Peat is found throughout the world. Canada and Finınd are among the countries with the largest deposits. efore its breakup, the Soviet Union was the largest eat producer. Ireland, Germany, and other countries roduced smaller amounts. The largest peat deposits in ıe United States are located in Minnesota. There are lso other peat *bogs* (marshes) in the United States, such s the Dismal Swamp in Virginia (see **Dismal Swamp**).

Most peat is harvested by machine. The machines ig, chop, and mix the peat and form it into blocks. The locks are then spread on the ground for drying. Some eat is still dug and stacked by hand.

Dried peat is used mainly as a fuel in places where oal and oil are scarce. In Ireland, for example, peat is a ıajor source of fuel to generate electricity. Peat is not sed as a fuel in the United States because of the high ost of drying it. Black peat is used as a fertilizer. Fluffy brown peat is used as a packing material, and as bedding for farm animals. Ray E. Ferrell, Jr.

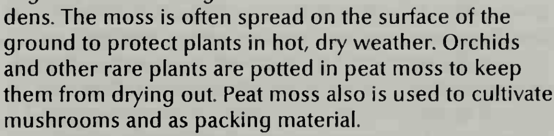
eat bogs furnish much of the fuel used in Ireland. The peat is arvested in blocks and dried before it is burned.

Peat moss is a kind of moss from which peat is formed. Peat consists of partially decayed mosses and other plant matter that accumulate over long periods of time in marshy areas called *bogs* (see **Peat**). Peat mosses make up a *genus* (scientific group) called *Sphagnum* and are often referred to as *Sphagnum mosses.* About 200 species of peat mosses are found in bogs throughout Canada, Siberia, and northern Europe.



Peat mosses grow up to 20 inches (50 centimeters) high. They typically grow close together and form dense mats that vary in color from dark-brown and red to yellow-green. Peat mosses are soft and spongy and have no true roots. They absorb and hold water in large dead cells in the stems and leaves. These cells can store large quantities of water for long periods of time. Peat mosses also can make surrounding soil more acidic and thus delay the growth of fungi.

Runk/Schoenberger from Grant Heilman

Peat moss usually grows in swamps. It is soft and spongy, forming dense mats that vary in color.

Peat moss is often used in greenhouses and gardens. The moss is often spread on the surface of the ground to protect plants in hot, dry weather. Orchids and other rare plants are potted in peat moss to keep them from drying out. Peat moss also is used to cultivate mushrooms and as packing material.

Scientific classification. Peat mosses belong to the family Sphagnaceae. They make up the genus *Sphagnum.*

Pecan, *pih KAHN* or *PEE kan,* a tree native to North America, is valuable for its fruit, the pecan nut. The pecan is a type of hickory. It grows naturally in the Mississippi Valley region from Iowa southward, and in the river valleys of Oklahoma, Texas, and northern Mexico. But pecan orchards are planted throughout the Southern United States as far north as Virginia, and in California. In addition, a small number of pecans are grown commercially in Australia, South Africa, and the Middle East.

Pecan raising is an important U.S. industry, especially in the South. Pecan orchards produce about 250 mil-

lion pounds (113 million kilograms) of nuts in an average year. About four-fifths of them are marketed as shelled nuts. Some pecan trees produce up to 500 pounds (230 kilograms) of nuts each year. But the trees do not bear nuts until they are about five or six years old. For another five years, they do not bear enough nuts to be profitable. Only after the trees are about 20 years old does the owner receive full return on the investment. Although the pecan is chiefly grown for its fruit, its wood is valuable for flooring, furniture, and paneling.

Pecan trees may grow 180 feet (55 meters) high. Their trunks are sometimes 4 to 6 feet (1.2 to 1.8 meters) in diameter near the ground, but most trees are smaller. The light brown or gray bark of pecan trees is deeply furrowed. The leaves are 12 to 20 inches (30 to 51 centimeters) long. They are made up of from 9 to 17 lance-shaped leaflets.

Pecan orchard trees are usually grown by grafting branch buds from trees that bear fine quality nuts on seedling stocks. In addition, pecan growers may manage and harvest nuts from groves of wild pecan trees. Pecan flowers are pollinated by the wind. However, most varieties of pecan trees are not pollinated by their own kind. For this reason, pecan orchards usually contain several different kinds of pecan trees. The thin-shelled pecans, which are called *papershell,* are a popular type because their shells can be cracked between the fingers.

Growers harvest the pecans after they fall to the ground. The nuts may fall naturally or be shaken off the trees using mechanical shakers. They are taken to processing centers where they are cleaned, graded, and packaged. The shelled nuts are cracked and most often sorted by machines. Richard A. Jaynes

Scientific classification. Pecans belong to the walnut family, Juglandaceae. They are *Carya illinoensis.*

Peccary, *PEHK uhr ee,* is a hoofed animal that lives in forests and desert scrublands. It is distantly related to the wild hog. There are three living species of peccaries: (1) the *collared peccary,* or *javelina;* (2) the *white-lipped peccary;* and (3) the *tagua,* or *Chacoan peccary.* The collared peccary lives in many sections of South America and as far north as the Southwestern United States. The white-lipped peccary is found in an area from central Mexico south to Paraguay. The tagua lives in the Gran Chaco region of Paraguay, Argentina, and Bolivia. Scientists discovered the tagua in 1975. They had previously thought that this species had become extinct more than 10,000 years ago.

Peccaries look much like slender hogs. The collared peccary stands about 21 inches (53 centimeters) high at the shoulder. It has a coarse, grizzled, blackish-gray coat with a gray collar. The white-lipped peccary is larger and darker. It is marked by white patches that extend from the mouth along the side of its face. The tagua, the largest living species, stands about 30 inches (76 centimeters) high at the shoulder. It has a coat of brownish-gray bristles with a gray collar. Peccaries have a large gland on their arched back, about 8 inches (20 centimeters) in front of the tail. When the animal becomes excited, the gland gives off a small amount of *musk,* a substance with a strong odor. For this reason, peccaries are sometimes called *musk hogs.*

The mother peccary usually gives birth to twins, which are about the size of rabbits. The young have reddish coats with a black stripe down their backs.

Peccaries feed chiefly on roots, but they sometimes prey on small animals. They travel in bands that may have up to several hundred individuals. They are shy, timid animals that flee from danger whenever possible. But if cornered, they fight viciously with their sharp teeth. Their most common natural enemy is the jaguar. Pigskin jackets and gloves are made from the thin, tough hides of peccaries. The skin can be recognized because the hair roots leave a pattern of three holes in evenly distributed groups. Jerry F. Downhower

Scientific classification. Peccaries make up the family Tayassuidae. The scientific name for the collared peccary is *Tayassu tajacu;* the white-lipped peccary is *Tayassu peccari;* and the tagua is *Catagonus wagneri.*

Peck is a unit of dry measure that is equal to 8 quarts or a quarter of a bushel (0.0088 cubic meter). Dry foods, such as potatoes and beans, are measured by the peck.

Peckham, Rufus W. (1838-1909), was an associate justice of the Supreme Court of the United States. Peckham believed in as little government interference with business as possible, and opposed many reform and welfare measures. He was noted for his opinion in the 1905 *Lochner v. New York* case, in which he voted with majority of the court to overrule a law that limited bakers to a 60-hour workweek (see **Lochner v. New York**).

Peckham was born in Albany, New York. He began to practice law in New York in 1857. He was elected to the New York Supreme Court in 1883. Later, in 1886, Peckham was elected to the State Court of Appeals. President Grover Cleveland named him to the Supreme Court of the United States in 1895, and he served from 1896 until his death in 1909. Stanley I. Kutler

Pecos Bill, *PAY kuhs* or *PAY kohs,* is a cowboy hero American folklore and popular tradition. He was the legendary inventor of roping, branding, and other cowboy skills. He also invented the six-shooter and train robbery and taught broncos how to buck.

According to legend, Pecos Bill was born in eastern Texas during the 1830's. He used a bowie knife as a

eething ring and played with wild animals. During a trip vest, Bill fell out of the family wagon near the Pecos River. He became lost and was raised by coyotes.

To win a bet, Pecos Bill once rode an Oklahoma cyclone without a saddle. The cyclone could not throw him and finally "rained out" from under him in Arizona. The rain fell so heavily that it created the Grand Canyon. Bill crashed in California, and the force of his fall created Death Valley. There are several versions of Bill's death. In one, he laughed to death after a man from Boston asked him silly questions about the West.

The legend of Pecos Bill developed from a magazine article written in 1923 by Edward O'Reilly, an American journalist. O'Reilly patterned Bill after Paul Bunyan and other legendary frontier heroes. Ellen J. Stekert

Pecos National Historical Park, *PAY kuhs* or *PAY kohs,* in north-central New Mexico, contains ruins of the ancient *pueblo* (village) of Pecos. It also includes the remains of two Spanish missions built in the 1600's and 1700's. The Pecos ruins became a landmark on the Santa Fe Trail. The site became a national monument in 1965 and was reclassified as a national historical park in 1990. For the area of the park, see **National Park System** (table: National historical parks).

Pecos River, *PAY kuhs* or *PAY kohs,* is the largest branch of the Rio Grande. The Pecos starts near Santa Fe, New Mexico, in the southern Sangre de Cristo Mountains. For most of its 800-mile (1,300-kilometer) course, the Pecos flows southeast. It runs beside the western palisade of Llano Estacado, a great plateau in New Mexico and Texas. It flows into the Rio Grande in Texas, near the town of Del Rio. It drains over 33,000 square miles (85,500 square kilometers). Reservoirs built along the river for irrigation include Lakes Avalon, McMillan, Red Bluff, and Sumner. For location, see **Texas** (physical map). Daniel D. Arreola

Pécs, *paych* (pop. 172,177), is an industrial center in the coal- and uranium-mining region of southwest Hungary. For location, see **Hungary** (political map). Pécs stands on the site of an ancient Roman settlement. Hungary's first university was founded at Pécs in 1367. Other landmarks include a cathedral built in the 1000's and several structures built by the Turks, who occupied the city during the 1500's and 1600's. Thomas Sakmyster

Pectin, *PEHK tuhn,* or *pectinic acid,* is a substance found in the cell walls of many fruits and some vegetables. Pectin binds cells to one another and provides firmness in the fruit or vegetable. It is used as a gelling agent in many processed foods and as a thickener in such foods as jelly, jam, preserves, and relish. Pectin provides dietary fiber but has no other nutritional value. It belongs to the carbohydrate group of foodstuffs, which includes starches and sugars.

The amount and type of pectin in a fruit depends on the species. Some fruits, including apples, currants, grapefruit, oranges, and plums, contain a large amount of the kind of pectin that causes gelling. When such fruits are cooked to make jelly or jam, the pectin forms a network of fibers that thicken the fruit juices. The pectin in other fruits, such as apricots, cherries, pineapples, and strawberries, does not cause these fruits to gel when they are cooked. However, commercial pectin can be added to thicken the mixture. Commercial pectin, available as a liquid or powder, is made from the rinds of apples and citrus fruits, especially lemons and oranges. Pediatrics is the branch of medicine concerned with the health of children. It deals with all aspects of a child's physical and emotional development and well-being, including the treatment of diseases and disabilities. It frequently involves preventive health care. Doctors who practice pediatrics are called *pediatricians.* These doctors provide care for children from birth through adolescence.

Pediatrics developed as a branch of medicine because many health problems occur chiefly or only in children. For example, chickenpox affects far more children than adults. Children are physically and psychologically different from adults, and so doctors must treat them differently. Children also grow rapidly and thus they change more quickly than do adults.

After graduating from medical school, a doctor who wishes to become a pediatrician must complete at least three years of special training in health care for children. The doctor then can become a certified pediatrician by passing an examination given by a pediatrics specialty board. Many pediatricians take two to three years of additional training in a particular area of pediatrics. For example, they may specialize in blood diseases or cancer; in certain organ systems, including the heart, kidneys,

or lungs; or in patients in specific age groups, such as newborns or adolescents. Such subspecialists act as consultants to other doctors and often conduct research on growth and development or on the treatment of disease. Gerald B. Merenstein

Pedicab, *PEHD uh KAB,* is a type of three-wheeled vehicle used as a taxicab. It is similar to a bicycle, but it has two rear wheels instead of one. It also has a passenger carriage that sits above the rear wheels. The carriage is often covered and partially enclosed. The driver sits on a bicycle seat and pushes pedals that turn the rear wheels. The driver guides the pedicab with bicycle handle bars.

E. R. Degginger

The pedicab was once widely used as a taxicab in many cities in Asia. Today, pedicabs are popular with tourists.

Pedicabs replaced *jinrikishas,* the hand-pulled carts once widely used as taxicabs in China, Japan, and other Asian countries (see **Jinrikisha**). Autos have replaced pedicabs in the major cities of Asia. Robert C. Post

Pedigree, *PEHD uh gree,* is a record of the ancestors of an animal or plant. To be most useful, a pedigree should record *traits* (characteristics) of the ancestors as well as their names and their birth and death dates. Breeders use pedigree information to predict such traits as size, strength, and color of hair in offspring. This information is considered so important in the improvement of livestock that breeders' associations have been formed to record the pedigrees of animals used for breeding. These animals are then said to be *registered.*

Pedigrees of plants are also helpful. But they are usually made for groups rather than individual plants. Hybrid corn breeders are careful to select and preserve known *pedigree lines* (families) of corn. Records of human ancestry are sometimes called *family trees.* The study of some family pedigrees enables scientists to predict the inheritance of certain diseases and physical defects. See **Genealogy**. George B. Johnson

Pedometer, *pih DAHM uh tuhr,* is a small instrument that measures the distance a person walks. The pedometer may be either mechanical or electronic. It is usually worn on the belt. With each step, the motion of the body causes a small lever to move. This lever records the number of steps taken. To find out how far you have walked, you must find the average length of your step and multiply it by the number of steps recorded. In some pedometers, a mechanism accounts for the length of the step, and measures the distance walked.

Pedro I, *PAY droh* or *PAY throo* (1798-1834), was the first emperor of independent Brazil. He ruled from 1822 to 1831.

Pedro was born on Oct. 12, 1798, in Lisbon, Portugal. He was the son of Prince John (later King John VI) of Portugal. In 1807, the Portuguese royal family fled to Brazil, a colony of Portugal, to escape capture by invading French troops. In 1821, John returned to Lisbon. He left Pedro to rule Brazil as prince regent.

Pedro was strongly influenced by a group of Brazilian-born counselors who favored independence for Brazil. On Sept. 7, 1822, he declared Brazil's independence. He was crowned emperor a few months later.

In 1826, John VI died, and Pedro became King Pedro IV of Portugal. Later that year, Pedro gave up the Portuguese throne in favor of his daughter, who eventually ruled Portugal as Maria II. Strong-willed and undemocratic, Pedro became increasingly unpopular in Brazil. In 1831, he gave up the throne in favor of his son Pedro II and returned to Portugal. Robert M. Levine

Pedro II, *PAY droh* or *PAY throo* (1825-1891), was emperor of Brazil from 1831 to 1889. During his rule, Brazil experienced modernization and economic progress, as well as the abolition of slavery.

Pedro was born on Dec. 2, 1825, in Rio de Janeiro. His grandfather was King John VI of Portugal. His father, Pedro I, became the first emperor of independent Brazil in 1822. Before then, Brazil had been a colony of Portugal.

In 1831, Pedro I gave up the throne, and Pedro II became emperor. Elected officials headed the government until 1840, when Pedro was declared old enough to rule on his own. Pedro gained respect as a moderate and humane ruler. Under him, Brazil helped overthrow Argentina dictator Juan Manuel de Rosas in 1852. In 1867, Pedro's government opened the Amazon River to world commerce. Between 1871 and 1888, his government passed a series of acts abolishing slavery in Brazil. This action cost Pedro the support of Brazil's great landowners. In 1889, the army forced Pedro to give up the throne and formed a republic. Robert M. Levine

Peel, Sir Robert (1788-1850), was a famous British statesman. He founded the London police force in 1829. The police have been called *bobbies,* after Peel's nickname, ever since. Peel also served as Britain's prime minister in 1834 and 1835 and from 1841 to 1846.

Peel was born on Feb. 5, 1788, near Bury, the son of a wealthy textile manufacturer. He attended Harrow School and Christ Church College of Oxford University, where he earned honors in classics and mathematics. When Peel was 21 years old, he made his brilliant first speech in the House of Commons. This speech led to his appointment as undersecretary for war and the colonies.

He maintained order by es-ıblishing an Irish police force, whose members were ommonly called *Peelers.* His strong opposition to mancipation of Roman Catholics helped keep Catholics ·om holding seats in Parliament until 1829. Such per-onal bitterness over the Catholic question grew up be-ween Peel and Daniel O'Connell, the Irish leader, that ıe two nearly dueled.

In 1819, Peel headed a commission to study British urrency. He recommended important reforms that ave the United Kingdom a sounder currency system. le became home secretary in 1822, but resigned in 827 when George Canning became prime minister, be-ause they disagreed on the Roman Catholic question. ı 1828, Peel returned to office under the Duke of Vellington. Peel organized the London police force in 829 to aid in enforcing the criminal code, which he elped revise and reform. In the same year, the political ituation caused him to change his mind on the Roman Catholic question. He helped prepare and pass the Catholic Emancipation Act, which allowed Catholics to old seats in Parliament and most government offices.

Pegasus, *PEHG uh suhs,* was an immortal winged horse in Greek mythology. He was the offspring of Medusa, a monstrous, snake-haired woman, and Posei-don, god of horses and of the sea. The hero Perseus slew Medusa by cutting off her head. Pegasus sprang full-grown either from her head or neck, or from the blood from her neck.

The hero Bellerophon wanted to tame Pegasus. A prophet advised him to sleep on the altar of the god-dess Athena. There, Bellerophon dreamed that the god-dess gave him a golden bridle and ordered him to make a sacrifice to Poseidon. When he awoke, Bellerophon

found a bridle on the altar. He sacrificed a bull to Posei-don and later came upon Pegasus at a spring, waiting to be bridled.

Bellerophon rode Pegasus on many adventures. Their most famous feat was destroying the fire-breathing Chimera (see **Chimera**). Bellerophon attempted to ride Pegasus up to Mount Olympus, the heavenly home of the gods. Zeus, king of the gods, was angered by the mortal's presumption in attempting to reach the heav-ens. Zeus sent a gadfly to sting Pegasus. The horse bucked, throwing Bellerophon down to earth and per-manently crippling him. Pegasus arrived on Olympus without a rider. The horse remained there, carrying Zeus's lightning and thunderbolts. Nancy Felson

Pei's John F. Kennedy Library in Boston is built of white concrete and glass. The nine-story structure emphasizes the broad, irregular geometric shapes that are typical of Pei's designs.

Pei, *pay,* **I. M.** (1917-), is an American architect noted for his creative urban designs. These designs include skyscrapers, housing projects, museums, and academic and government buildings. Pei's buildings are characterized by broad irregular geometric shapes and large open interiors.

Ieoh Ming Pei was born in Guangzhou (also called Canton), China, and came to the United States in 1935 to study architecture. He became a U.S. citizen in 1954. Pei's early works show the influence of the modern German architects Walter Gropius and Ludwig Mies van der Rohe. These works include the Mile High Center (1955) in Denver, Colorado, and the Society Hill housing project (1964) in Philadelphia.

In the late 1960's, Pei began to develop a more personal style using prism shapes. His later projects include the National Center for Atmospheric Research (1967) in Boulder, Colorado; the Everson Museum of Art (1968) in Syracuse, New York; the John Hancock Building (1973) in Boston; the East Building (1978) of the National Gallery of Art in Washington, D.C.; and the John F. Kennedy Library (1979) in Boston. In 1989, Pei completed the glass pyramid that serves as the entrance to the Louvre museum in Paris. His Rock and Roll Hall of Fame and Museum in Cleveland opened in 1995. Pei also designed the Miho Museum (1997) near Kyoto, Japan. Nicholas Adams

Peirce, *purs,* **Charles Sanders** (1839-1914), was an American philosopher. He helped lead a philosophical movement called *pragmatism.* Peirce, who was probably the foremost logician of his time, pioneered in the development of mathematical logic. In addition, Peirce helped develop *semiotics,* the study of how human beings use various signs and symbols, including words.

Peirce discussed the basic ideas of his pragmatism in an essay called "How to Make Our Ideas Clear" (1878). To understand an idea, he declared, we need to consider the behavior of objects to which the idea refers. For example, if we say that a diamond is "hard," we should want to know what this idea means. Therefore, we should find out what a diamond can do—such as scratch a piece of glass without being scratched itself. We understand what we mean by a diamond if we know what it does do, could do, and might do under various circumstances. The meaning of an object, according to Peirce, includes how we are likely to behave in its presence.

Like other pragmatists, Peirce wanted to connect thought and action. He believed that our thoughts should produce beliefs upon which we can act confidently. If we are in doubt, we hesitate to act. Doubt forces us to inquire into things until we have a belief. If we are not able to clear up our doubts with further inquiry, we must act on the belief most likely to be true.

Peirce was born in Cambridge, Massachusetts. His father, the famous mathematician Benjamin Peirce, introduced him to the study of science and philosophy. Peirce graduated from Harvard University in 1859 and did scientific work for the United States Coast Survey from 1861 to 1891. These scientific studies stimulated his interest in philosophy. During his career, Charles Peirce also expressed original ideas about evolution, the role of chance in the universe, the human mind, and the reality of God.

Peirce did not present his philosophy in any organized fashion, and so he received little recognition during his lifetime. Years after his death, however, several philosophers published Peirce's works in eight volumes called *The Collected Papers of Charles Sanders Peirce.*

Peking fossils, *pee KIHNG,* are the remains of a type of prehistoric human being who lived between about 600,000 and 400,000 years ago in what is now northern China. Scientists named these people *Sinanthropus pekinensis,* which means *Chinese person of Peking.* The Peking people belong to a species of human beings called *Homo erectus* (erect human being).

In the 1920's, Davidson Black, a Canadian anatomy professor, identified fossils found near Beijing (also spelled Peking), China, as remains of prehistoric human beings. Since then, scientists have found the partial remains of more than 30 of these prehistoric people, along with more than 100,000 stone tools and countless animal bones, mainly those of deer.

The fossils show that the Peking people stood about 5 feet 1 inch (155 centimeters) tall and had heavy bones. These people apparently had big browridges, powerful jaws, large teeth, and a brain smaller than that of modern people.

In 1941, most of the fossils disappeared while being shipped out of China. In 1963 and 1964, scientists found similar fossils at Lantian (Lan-t'ien), about 600 miles (970 kilometers) southwest of Beijing. Karl W. Butzer

'elican, *PEHL uh kuhn,* is a large bird that lives near vater. Pelicans have a long, straight bill with a flexible ouch made of skin on the underside. They use the ouch to catch fish, their chief food. Pelicans also eat ther animals, such as salamanders and frog tadpoles. he birds have webbed feet and can swim well. They lso are skilled fliers, but they are clumsy on land.

Kinds. There are seven species of pelicans. Five have vhite feathers with some black on the wings. Of the re-iaining two kinds, one is gray and white, and the other brown. The brown species, or *brown pelican,* inhabits oasts of North and South America. The six other spe-ies live along rivers and near freshwater lakes in North merica, Europe, Africa, Asia, and Australia. They in-lude the *American white pelican* and *Australian pelican.*

The American white pelican weighs about 16 pounds 7 kilograms) and is about 5 feet (1.5 meters) long. It has a vingspread of up to 10 feet (3 meters). The bird nests in vestern and central North America. It migrates in the fall s far south as Mexico and Central America.

The Australian pelican, the largest pelican species, rows to about 6 feet (1.8 meters) long and weighs up to 4 pounds (15 kilograms). Its wingspread reaches over 8 eet (2.4 meters). This pelican lives throughout Australia.

The brown pelican lives as far north as North Carolina nd British Columbia. It ranks as the smallest species of elican. It measures about 4 feet (1.2 meters) long and has a wingspread of about 7 feet (2 meters).

Habits. American white pelicans often fish in groups. They swim along the top of the water in a line, driving the fish ahead of them. After the fish have been chased into shallow water, the pelicans scoop up the catch with their pouches. The brown pelican flies until it spots a fish near the surface of the water. Then it dives into the water to catch the fish.

Pelicans are almost always seen in flocks. While flying, American white pelicans may gather in flocks of up to 1,000 birds. These birds may soar upward in tight circles on a rising current of hot air called a *thermal.*

Pelicans nest in large *colonies* (groups). Some peli-cans nest in trees. They build their nests out of twigs and other plant materials. Other pelicans nest in small hollows on the ground, usually on islands. Female peli-cans lay two or three chalky-white eggs, which hatch in about a month. Pelicans are born without feathers. They cannot fly until they are about 10 to 12 weeks old.

Pelicans and people. Housing and commercial de-velopments have endangered pelicans in many parts of the world. Such developments often pollute the peli-cans' feeding grounds and destroy their nesting sites. Two of the most endangered pelican species, the *Dal-matian pelican* of Europe and Asia and the *spot-billed pelican* of south and southeast Asia, have seen much of their natural habitat destroyed by human development.

People have also reduced pelican populations be-cause they perceived the birds as a threat. For example, American white pelicans were killed because fishermen believed the birds ate game fish. Studies of white peli-cans, however, have proven this belief to be untrue.

Over the years, people have worked to conserve peli-cans in many ways. In 1903, United States President Theodore Roosevelt set up the first U.S. national wildlife refuge—Pelican Island, in Florida—to protect nesting

Pellagra, *puh LAG ruh* or *puh LAY gruh,* is a disease caused by a lack of niacin and other B-complex vitamins (see **Vitamin** [Vitamin B complex]). Corn is a poor source of niacin, and many people who eat corn as the main part of their diets develop pellagra. In the early 1900's, American physician Joseph Goldberger proved that pellagra was associated with diet (see **Goldberger, Joseph**).

Today, pellagra occurs chiefly in developing nations where corn and corn products are the major food source. It also may affect people who do not have a proper diet, especially the poor and people dependent on alcohol or drugs.

Early symptoms of pellagra include weakness, lack of appetite, diarrhea, and indigestion. *Dermatitis* (skin inflammation) develops especially on body parts exposed to sunlight, heat, friction, or other irritants. The tongue becomes swollen and sore, and *lesions* (skin eruptions) develop in and around the mouth. Later symptoms include anxiety, headaches, irritability, and sleeplessness. In extreme cases, severe psychosis may develop.

Pellagra is treated by changing the diet so that it includes a sufficient amount of protein-rich foods, such as meat, fish, eggs, and milk and milk products. These foods are good sources of niacin or of the amino acid *tryptophan,* which the body converts into niacin. In some cases, physicians prescribe niacin tablets for patients with pellagra. Pelopidas, *puh LAHP ih duhs* (? -364 B.C.), was a general and statesman in ancient Thebes. In 382 B.C., the Spartans seized Thebes, and Pelopidas fled. Returning in 379 B.C., he drove the Spartans out. Aided by Epaminondas, another general, he trained the Thebans in military discipline and strategy. Pelopidas led a group of 300 soldiers called the *Sacred Band.* He also helped reorganize the Boeotian and Thessalian leagues, two former groups of Greek cities that had become inactive. Pelopidas and Epaminondas led the Boeotian League to victory over Sparta in the Battle of Leuctra in 371 B.C., making Thebes the most powerful state in Greece. In 364 B.C., Pelopidas was killed in battle. Epaminondas died in war two years later, and Thebes's supremacy collapsed. Linda J. Piper

Peloponnesian War, *PEHL uh puh NEE shuhn,* was fought by the ancient Greek city-states of Athens and Sparta from 431 to 404 B.C. According to Thucydides, a Greek historian who lived during the war, the Peloponnesian League, consisting of Sparta and its allies, attacked the Athenian empire because it feared the growing power of Athens.

The war was divided into three parts: (1) *The Archidamian War* (431-421 B.C.) was named for Archidamus, the Spartan king who led annual attacks on Athens. He hoped to force a surrender, but the Athenian navy successfully defended the city, which was also protected by walls. (2) *The Peace of Nicias* (421-413 B.C.) was arranged by Nicias, an Athenian politician. It was broken when Athenian commander Alcibiades persuaded Athens to attack the Peloponnesian League in 418 B.C. and Sicily in 415 B.C. Both attacks failed. (3) *The Decelean* or *Ionian War* (413-404 B.C.) ended in victory for Sparta. Sparta gained Persia's support, helped subjects of Athens revolt, and forced Athens to surrender. Peter Krentz

Peloponnesus, *PEHL uh puh NEE suhs,* is the ancient name of the southern peninsula of Greece. It was linked to the mainland by the Isthmus of Corinth and was sometimes called the "island of Pelops." In ancient times the Peloponnesus consisted of six divisions: Achaea, Arcadia, Argolis, Elis, Laconia, and Messenia. In medieval times it was known as Morea. Peter Krentz

Pelosi, Nancy (1940-), became the *whip* (assistant leader) of the Democrats in the United States House of Representatives in 2002. The post is the highest congressional office ever held by a woman. Pelosi has been a congresswoman from California since 1987, representing San Francisco.

As a member of the House, Pelosi became known for her liberal views. She has opposed closer trade relations with China because she disapproves of that country's human rights record. She also played a role in increasing government funding for AIDS research.

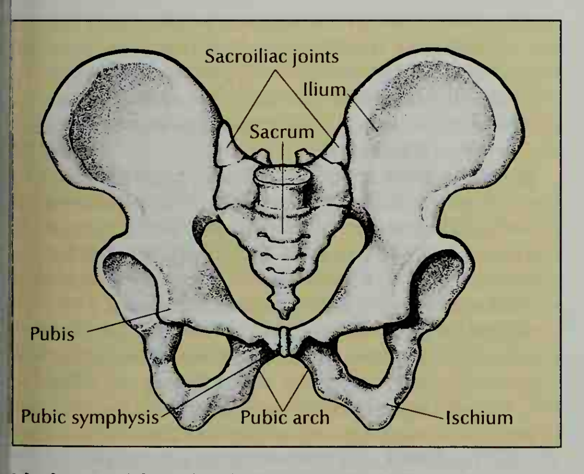
Nancy Pelosi

Pelosi was born Nancy Patricia D'Alesandro in Baltimore. Her father, Thomas D'Alesandro, Jr., was a Democratic member of the U.S. House of Representatives at the time of her birth and later served as mayor of Baltimore from 1947 to 1959. Her brother Thomas also served as Baltimore mayor, from 1967 to 1971.

Nancy D'Alesandro graduated from Trinity College in Washington, D.C., in 1962 with a bachelor's degree in history and political science. In 1963, she married Paul F. Pelosi, who became a successful investor. She served as chair of the California Democratic Party from 1981 to 1983. Jeremy D. Mayer

Pelvic inflammatory disease, often referred to as *PID,* is an infection of the female reproductive system. It affects a woman's uterus and fallopian tubes, both of which are located in the pelvic cavity. PID is caused by several bacteria, particularly the ones that cause gonorrhea and chlamydia. In most cases, the bacteria enter a

woman's body during sexual intercourse with an infected male. If untreated, the disease can lead to infertility and, in rare cases, death.



Many patients with acute PID experience symptoms during or shortly after their menstrual period. Symptoms include lower abdominal pain, vaginal discharge, fever, and nausea. Patients notice tenderness of the uterus, fallopian tubes, and ovaries upon examination by a physician. In severe cases, patients may have an *abscess* (collection of pus) in the infected area. PID also is a primary risk factor for *ectopic,* or *tubal, pregnancy,* a potentially fatal condition in which a fertilized egg starts developing in a fallopian tube instead of in the uterus.

Women with mild cases of PID can be treated with antibiotics as outpatients. Those with severe PID should be hospitalized and given antibiotics intravenously. Patients with an abscess may need surgery. Patrick Duff

Pelvis is the bony structure that supports the lower abdomen. It surrounds the urinary bladder, the last portion of the large intestine, and, in women, the reproductive organs. A female's pelvis is flatter and broader than a male's, and it has a larger central cavity.

The spinal column joins the pelvis at the *sacroiliac joints.* The *femurs* (thigh bones) join the lower part of the pelvis in large ball-and-socket hip joints that allow the legs to move in many directions. Many large muscle masses lead from the pelvis to the femurs.

The bones of the pelvis form a basinlike structure.

Two big, symmetrical hipbones form the pelvis. These bones join in front to form the *pubic symphysis.* In back, they form a strong union with the *sacrum* (five backbones joined to form a single bone). Each hipbone in an adult appears to be one solid bone. But it is formed by three bones, the *ilium, ischium,* and *pubis,* that unite as the body matures. The ilium is the broad, flat bone you feel when you rest your hand on the hip. When you sit down, much of your weight rests on the ischium. The pubis bones form two arches in front that join at the symphysis. Madison B. Cole, Jr.

Pembroke Welsh corgi, *PEHM bruk WEHLSH KAWR gee,* is a breed of dog that originated in the area of Pembroke, Wales, during the early 1100's. The Celtic people used these dogs to drive cattle and for other farm work. Pembroke Welsh corgis are the smallest of the group of breeds called *herding dogs.* They stand from 10 to 12 inches (25 to 30 centimeters) high and weigh from 18 to 30 pounds (8 to 14 kilograms). Pembrokes have thick coats that protect them from all kinds of weather. The dogs are generally yellowish- or reddish-brown and may have white patches on the head, neck, chest, and legs. Some Pembrokes have black and tan coats. Pembrokes are considered highly intelligent, and they make affectionate pets.

The Pembroke Welsh corgi resembles the Cardigan Welsh corgi. But the Pembroke has a slightly shorter body, a finer-textured coat, and a much shorter tail.

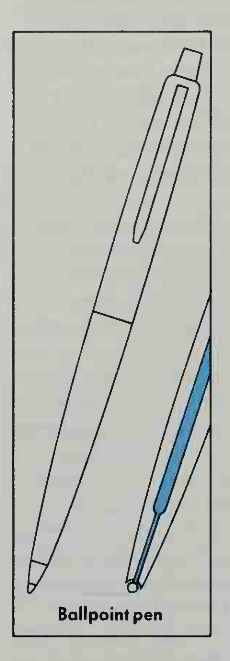
Pemmican, *PEHM uh kuhn,* was one of the first forms of concentrated food. North American Indians made it from dried buffalo or deer meat. The Indians often hung the meat at the top of a tepee to dry over a campfire, which gave the meat a smoky flavor. They pounded the dried meat into a powder and mixed it with hot fat. When this mixture cooled, it was cut into cakes. Sometimes berries were added for flavor. Pemmican served as the main food when the tribes migrated. Pemmican keeps almost indefinitely and takes up little room.

Today, explorers, surveyors, hunters, and others often take pemmican with them on long trips. Pemmican is now usually made of beef. The people of South America make *tasajo,* which is much like pemmican, as is the *biltong* of South Africa. Helen C. Brittin

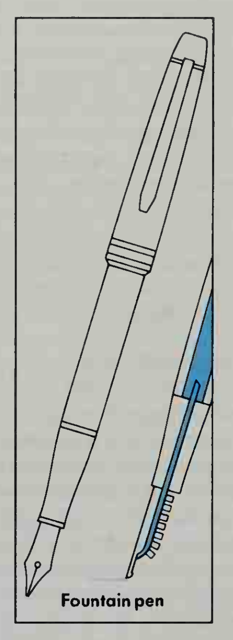
Pen is an instrument used for writing or drawing with ink. Pens of one type or another have been used for thousands of years. Today, pens rank among the most widely used writing instruments. The world's pen manufacturers produce billions of pens annually.

There are five main kinds of pens. They are (1) ballpoint pens, (2) fountain pens, (3) soft-tip pens, (4) roller ball pens, and (5) specialty pens.

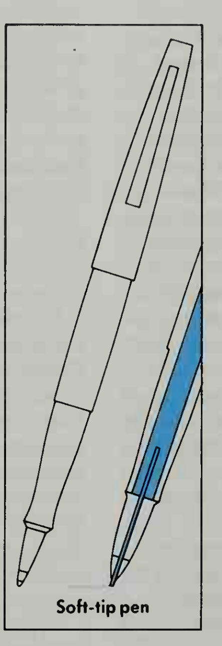
Ballpoint pens have a tiny ball made of brass, steel, or tungsten carbide as their writing tip. A compartment called the *ink reservoir* holds the ink, and a narrow tube links the reservoir to the ball. The ball, which is fitted into a socket, turns as it rolls across the paper, carrying ink from inside the pen onto the paper. Many ballpoint pens have a plastic cap that helps prevent ink from drying out on the ball. On others, a push-button mechanism draws the pen point into the body of the pen.



Most ballpoint pens depend on gravity to pull the ink to the ball. For this reason, ballpoint pens generally do not write well when held sideways. However, some ballpoints are designed so that slight pressure is always applied behind the ink column. This design enables the ink to move constantly forward and the pen to write even when its point is higher than its back end. Ballpoint pens use a thick, sticky ink because a thinner ink would leak out around the ball. But the use of such ink makes ballpoint pens write less smoothly than most other pens.



Fountain pens have a somewhat triangular writing point, called a *nib,* which is made of gold or stainless steel. A system of narrow tubes known as the *feed* carries the ink from the pen's reservoir to the nib.



Fountain pens use a highly fluid ink. They rely on a property called *capillarity* to draw the ink into and

through the feed. Capillarity causes the inner surface of the tubes to attract molecules of ink. These ink molecules, in turn, attract other ink molecules, and the feed fills with ink from the pen's reservoir. See **Capillarity.**

The feed in a fountain pen also includes a number of air passages that lead to the reservoir. These passages allow air to fill the top of the reservoir as ink is drawn from the bottom. Thus the air pressure inside the pen remains equal to the air pressure outside the pen, and the ink flows easily. If the air pressure inside the ink reservoir is lower than the atmospheric pressure outside, the ink will not reach the point and the pen will fail to write. However, if the air pressure over the ink column becomes greater than the air pressure outside the pen, ink will flood out from the front of the pen. To avoid such flooding, fountain pens are designed with a *collector.* The collector, which is located near the nib, consists of a series of fins and spaces that provide enough additional room to accommodate forward moving ink.

Soft-tip pens, also called *porous-point pens,* have a relatively soft writing tip. Some soft-tip pens, called *felt-tip pens,* have a feltlike writing tip. The tip of others is made of absorbent plastic.

Soft-tip pens use fluid, brightly colored inks. The reservoir in a soft-tip pen consists of a synthetic material made up of many fibers. This *capillary reservoir* holds ink much as a sponge holds water. During writing, the absorbent tip of the pen draws ink from the reservoir onto the paper.

Roller ball pens combine certain features of ballpoint, fountain, and soft-tip pens. Like ballpoint pens, roller ball pens have a tiny ball that turns in a socket at their tip. But unlike ballpoints, roller ball pens use highly fluid inks, which allow them to write as smoothly as soft-tip and fountain pens.

Roller ball pens may have either a capillary reservoir similar to that used in soft-tip pens or a reservoir like that of ballpoints. A wick made of an absorbent material draws ink from the reservoir and carries it to the ball. The wick can carry only a limited amount of ink at any one time. In this way, the wick regulates the flow of ink and prevents it from leaking out.

Specialty pens are designed for specific purposes. For example, artists and mechanical drafters use a pen called a *technical pen.* This pen comes with a set of interchangeable pen points of varying widths. Another special pen, called a *lettering pen,* is used to create an elegant style of handwriting called *calligraphy.*

History. As early as 4000 B.C., ancient peoples used crude pens consisting of hollow straws or reeds that supported a short column of liquid. During the 500's B.C., people began to make pens from the wing feathers of such birds as geese and swans. The shaft of the feathers was hardened, and the writing tip was shaped and slit to make writing easy. These feather pens were known as *quill pens,* and they were widely used until the development of steel-nib pens in the 1800's.

By the late 1800's, inventors had perfected an early type of fountain pen. This pen represented a major advance because it had an ink reservoir and a capillary feed. Earlier pens held only a small amount of ink at a time and had to be repeatedly dipped in ink.

John H. Loud, an American inventor, patented a ballpoint pen in 1888. But ballpoint pens received little notice until World War II (1939-1945). Many pilots began using ballpoint pens during this conflict, because such pens did not leak at high altitudes. After the war, ballpoint pens became increasingly popular. Soft-tip pens and roller ball pens both were introduced in the 1960's.

Pen name is a name an author uses instead of his or her real name. Pen names are also called *pseudonyms.*

housands of authors use pen names. Most are popular ovelists who adopt one or more pen names to avoid ooding the market with many works published under ne same name. Writers sometimes use pen names to onceal their identity for legal reasons, to protect their rivacy, or because they are dealing with highly person- l or controversial material.

During the 1800's, many women writers adopted mas- uline pen names because of sexual discrimination. For xample, the British novelist Mary Ann Evans concealed er femininity with the pen name George Eliot.

Pen names first became common in the 1700's with ne emergence of newspapers, magazines, and other eriodicals. Authors adopted pen names because they eared political persecution for their writings. Perhaps ne most famous early pen name was Voltaire, which vas adopted in 1718 by the French writer François Aarie Arouet. The English writer Charles Dodgson vrote under the pen name of Lewis Carroll. The Ameri- an author Samuel Clemens used the pen name Mark wain. The children's writer Theodor Seuss Geisel used ne pen name Dr. Seuss. The American mystery writers rederic Dannay and Manfred B. Penal colony is a settlement outside a country where he country sends its prisoners. From the 1500's to the mid-1900's, many European nations operated penal colonies to help relieve overcrowded prisons and to re- move convicts to faraway places. Countries sometimes used the prisoners as laborers to develop the natural re- sources of a colony.

Britain sent many prisoners to the American Colonies n spite of the objections of colonists there. The Revolu- ionary War (1775-1783) ended penal colonies in Ameri- ca. The British then shipped criminals to Australia. These prisoners were the first white people to settle in Aus- ralia (see **Australia** [History]).

A well-known French penal colony was Devils Island n French Guiana. This colony was started by Napoleon II in 1852. In 1945, the prisoners at Devils Island were ransferred or liberated.

In the past, penal colonies were known for their bru- tal treatment of prisoners. The prisoners were often chained together and whipped. Today conditions have improved, but most of the remaining penal colonies are still places of harsh punishment. James O. Finckenauer

Making a cased pencil involves several steps. First, cedar logs are sawed into narrow slats (figure 1). Parallel grooves are cut into the slats (2). A graphite mixture is laid in the grooves of one slat (3), which is then glued to an empty slat (4). Individual pencils are cut from this pencil "sandwich" (5 and 6). Finally, an eraser is attached to the pencil by a ringlike *ferrule* (7).

tures, plans, maps, and diagrams. Astronauts have taken pencils into space because the writing ability of pencils is unaffected by gravity, pressure, or conditions in the atmosphere. Billions of pencils are produced annually throughout the world.

Pencils consist of a writing core made mostly of graphite set within a case of wood, metal, or plastic. There are three main types of pencils: (1) cased pencils, (2) colored pencils, and (3) mechanical pencils.

Cased pencils consist, in most instances, of a wood case and a black writing core. The core is composed of graphite and fine clay, sometimes combined with other chemicals. When graphite was first used in pencils, people mistakenly thought it contained lead. The graphite mixture is still called *lead* and the pencils, which contain no lead, are often called *lead pencils.*

Graphite for pencils is formed into spaghettilike strings, cut to precise measurements, and dried in ovens. Manufacturers vary the proportions of graphite and clay in the mixture to produce pencils with harder and softer writing cores. The Number 2 pencil is the standard and most common pencil used today. Pencils with numbers less than 2 have softer leads and contain less clay and more graphite. Soft pencils make a dark, heavy line. Harder pencils make a finer, lighter line.

Most cased pencils are made from incense-cedar. Cedar logs are sawed into narrow strips called *slats.* The slats are about 7 $\frac{1}{4}$ inches (18.4 centimeters) long, $\frac{1}{4}$ inch (6.4 millimeters) thick, and 2 $\frac{3}{4}$ inches (7 centimeters) wide. They are stained, waxed, and dried before shipment to the pencil factory. At the factory, parallel grooves are cut into one side of the slats and half of the slats are then coated with a fine layer of glue. Next the graphite is laid in the grooves of the glued slats, and pencil "sandwiches" are made. Pencil sandwiches are produced by pressing the empty slats onto the slats that already have graphite inserted in them. The sandwiches then go into a shaper, which forms the slats into individual *hexagonal* (six-sided) or round pencils. Most pencils are made into a hexagonal shape. The flat sides of such pencils prevent the pencils from rolling off surfaces.

After the individual pencils have been cut, they are painted. Yellow is the color most often used for pencils. Erasers are then attached to the pencils. Each eraser is surrounded by a round, metal case called a *ferrule,* which is held in place either by glue or by small metal prongs. Most ferrules are made of aluminum or steel.

Colored pencils are made in much the same way as black-writing pencils. But their cores contain such coloring materials as *dyes* and *pigments* instead of graphite.

Mechanical pencils have a metal or plastic case. They use leads similar to those used in cased pencils. Mechanical pencils require no sharpening. The lead rests inside a *spiral* (round coil) within the case and is held in place by a rod that has a *stud* (piece of metal) fastened to it. In most cases, depressing the end of the pencil causes the rod and stud to move downward in the spiral, forcing the lead toward the point. Some pencils work by other mechanical methods.

History. The earliest pencils date back to the ancient Greeks and Romans, who used flat cakes of lead to mark faint black lines on *papyrus* (an early form of paper) to guide writers. In the Middle Ages, people used thin rods of lead or silver for drawing.

The marking ability of graphite was discovered in the 1500's. By the early 1600's, cased graphite pencils were being made in Britain and Germany. In 1662, Frederick Staedtler established what can be considered the first pencil factory, in Nuremberg, Germany. Although Staedtler's workers made pencils by hand, they carried out all the steps in the production at one location.

In 1795, Nicholas Jacques Conte, a French chemist, developed a pencil of powdered graphite and clay. His mixture proved to be as smooth and hard as pure graphite. Conte also discovered that a harder or softer writing core could be produced by varying the proportions of clay and graphite.

In the 1800's, several inventors created machines for shaping and smoothing the wooden components of pencils. In 1822, Sampson Mordan, a British engineer, received the first patent for a mechanical pencil.

Penderecki, *pehn deh REHTS kih,* **Krzysztof,** *kruh ZIHSH tawf* (1933-), is a Polish composer. He became known for using unconventional instrumental and vocal sound effects in his works. For example, in his *String Quartet No. 1* (1960), the musicians slap their instruments and tap them with their bows. In *Dimensions of Time and Silence* (1960), a chorus sings only single-syllable consonants. In other works, singers hiss or whistle. His most famous piece is *Threnody for the Victims of Hiroshima* (1960) for 52 string instruments.

Penderecki has written several religious works, including *St. Luke Passion* (1966) and *Utrenja* (1970-1971). For the 25th anniversary of the United Nations, Penderecki wrote *Kosmogonia* (1970) for solo singers, chorus, and orchestra. Penderecki has composed two operas, *The Devils of Loudun* (1969) and *Paradise Lost* (1978). The latter opera reflects Penderecki's turn away from a dissonant style toward a more *neoromantic* style. He was born in Dębica. Stephen Jaffe

Pendergast, Thomas Joseph (1872-1945), was a Kansas City, Missouri, politician who rose from poverty to become one of the most powerful political bosses in the United States. He helped future United States President Harry S. Truman win several elections, including a run for the U.S. Senate in 1934.

Thomas (Big Tom) Pendergast was born to an Irish immigrant family in St. Joseph, Missouri. In 1911, he succeeded his brother James (Big Jim) Pendergast as the head of a Democratic Party political *machine* in Kansas City. A political machine is a group that does favors for citizens in return for votes. The Pendergast machine won elections by dispensing jobs and assistance. Members took money from illegal bribes. Pendergast ruled with an iron fist, using violence when necessary and making deals with gangsters and political officials. He won public favor by backing improvement projects that benefited Kansas City.

Violence, fraud, and corruption eventually caught up with the Pendergast machine. In 1937 and 1938, 259 machine members were convicted on federal vote fraud charges. Pendergast was sentenced to 15 months in jail and 5 years probation for tax evasion in 1939. Without his leadership, his machine fell from power.

'endulum, *PEHN juh luhm* or *PEHN dyuh luhm.* If an ›bject that pivots around a fixed point is pulled aside ınd let go, gravity makes it swing back and forth at a egular rate. Such a body is called a *pendulum.* The *sim- ɔle pendulum* consists of a weight hanging at the end of ı string or wire. The path traveled by the weight is :alled the *arc of the pendulum.* The *period of oscillation* s the time it takes the weight to pass back and forth ɔnce over this arc.

The period depends upon the pendulum's length and ocation. If a pendulum were taken from one place to ınother on the earth, the period would change slightly due to a change in the pull of gravity. For example, the ɔeriod would increase if the pendulum were taken from sea level to the top of a mountain. It increases because the force of gravity becomes weaker at greater heights. A simple pendulum 9.79 inches (24.87 centimeters) long has a period of 1 second at sea level.

If the swing is small, the period varies with the square root of the length of the pendulum. For example, the pe- riod of a 9-inch pendulum is $1\frac{1}{2}$ times as long as the pe- riod of a 4-inch pendulum. (The square root of 9 is 3, the square root of 4 is 2, and 3 is $1\frac{1}{2}$ times as large as 2.)

The equation that expresses this relationship is:

$$t = 2\pi\sqrt{\frac{l}{g}}$$

where t is time, the period of the pendulum, in seconds; l is the length of the pendulum in feet (meters); and g is the *acceleration due to gravity,* a factor that depends on the gravity where the pendulum is located. At sea level, g = 32.16 feet (9.802 meters) per second per second.

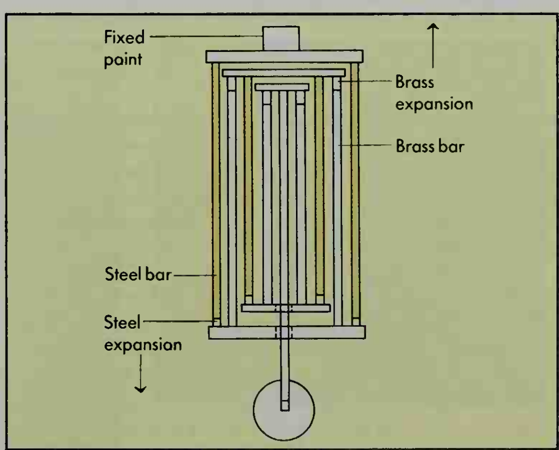
The Italian physicist Galileo discovered the laws of the pendulum. He noticed that a hanging lamp would swing with an almost constant period, whether the arc was large or small. He believed that a pendulum could regu- late the movements of clocks. The Dutch scientist Chris- tiaan Huygens patented the first pendulum clock in 1657. Galileo's observations are still correct as long as the pendulum's swing is small. But modern measuring in- struments have shown that the period of a pendulum in- creases when it has a large swing.

Clock pendulums usually consist of a rod with a heavy weight at one end and a hard bearing at the other. A screw at the end of the rod permits the weight, or *bob,* to be raised or lowered. When the bob is lowered, the pendulum swings more slowly, and the clock runs more slowly. When the bob is raised, the pendulum swings faster, and the clock runs faster.

The bearing on which the pendulum swings must be as nearly frictionless as possible. It is often made of a knife edge of agate set in a grooved agate plate.

A device called an *escapement* is fastened to the mechanism of the clock. It gives small but regular push- es to the pendulum and keeps it swinging. The escape- ment lets one tooth of a toothed-wheel turn past it each time the pendulum swings aside. This action gives the clock its "tick-tock" sound.

The rod in a clock pendulum tends to expand when it is warmed and to shorten when it is cooled. If no cor- rection is made, pendulum clocks will run slower in hot weather and faster in cold weather. Several means have been developed to make up for this effect. For example, clocks known as *regulators* usually come with so-called *gridiron* pendulums. These pendulums consist of sever- al brass and steel rods. The rods are arranged so that the brass rods raise the bob and the steel rods lower it as the temperature increases.



Other pendulums. In *torsion pendulums,* a wheel or a balanced set of weights is suspended on a wire. The wire becomes twisted like a spring as the weight rotates

around it. Torsion pendulums are used in the so-called 400-day clock and in other measuring instruments.

In *bifilar* (pronounced *by FY luhr*) *pendulums,* two parallel wires hold the bob. They are pulled tight to provide a more controlled motion. A bifilar pendulum is sensitive to variations of the *plumb line* (line toward the earth's center of gravity). Bifilar pendulums have been used to show that the earth does not rotate on its axis at a constant speed. Such changes in the earth's rotation result from the pull of gravity exerted on the spinning earth by the sun and moon.

In 1851, the French scientist Jean Foucault hung a large iron ball on a wire about 200 feet (60 meters) long. With this pendulum, he showed that the earth rotates on its axis. A Foucault pendulum is similar to a simple pendulum, but its motion is not limited to a plane. The plane of its swing appears to change as the earth goes through its daily rotation. However, the pendulum actually continues to move in the plane in which it was set in motion, while the earth turns under it. At the equator, a Foucault pendulum does not change its apparent plane of swing. The change would be fastest at the North and South poles (see **Coriolis effect**). James D. Chalupnik

Penelope, *puh NELL uh pee,* in Greek mythology, was the wife of Odysseus (Ulysses in Latin), king of Ithaca. She became famous for her faithfulness to her husband. After the birth of their son, Telemachus, Odysseus left on an expedition against Troy. He did not return for 20 years, but Penelope remained faithful to him. Her story is told in the epic poem the *Odyssey.*

Many nobles from Ithaca and neighboring islands courted Penelope, claiming that Odysseus would never return, but she refused to remarry. For three years, she held suitors off by a trick. She said that she must first weave a shroud for her father-in-law, Laertes. Each night she unraveled what she had woven that day.

After a maidservant revealed Penelope's deception, she promised to select the suitor who could string and shoot Odysseus's great bow. Each suitor tried and failed. A beggar, who had come to the palace and was given shelter, asked to try. He easily strung and shot the bow. The beggar was Odysseus in disguise. With the bow, he killed the suitors. Odysseus regained his kingdom and was reunited with Penelope. Cynthia W. Shelmerdine

Penfield, Wilder Graves (1891-1976), was a Canadian neuroscientist and physician who developed a surgical cure for some forms of epilepsy. In these forms, epileptic seizures originate in small clusters of damaged brain cells. Penfield developed techniques for locating damaged brain cells and removing them surgically.

Penfield also mapped the areas of the brain that control various bodily activities. He showed that the brain's control of such activities as speech and memory is temporarily stopped when electric currents are applied to certain parts of the brain. In this way, Penfield located a speech area of the brain in the rear of the left half of the cerebrum. He also discovered that electric stimulation of the *temporal lobe,* a part of the cerebrum, activated memories of earlier experiences. He concluded that some memory is stored in the temporal lobe.

Penfield was born in Spokane, Washington. He graduated from Oxford University in 1916 and received his M.D. degree from Johns Hopkins University in 1918. Penfield became a Canadian citizen in 1934. That year, he founded the Montreal Neurological Institute, which he directed until his retirement in 1960. Dale C. Smith

Penguin is a type of flightless bird that spends most of its life in the ocean. Penguins stand upright on land and walk with a waddle because they have short legs and tall, torpedo-shaped bodies. Penguins appear awkward out of the water, but they can walk about as fast as a human being. They also climb rocky slopes easily, sometimes hopping from rock to rock. Some penguins travel over ice and snow by *tobogganing* (sliding on their bellies).

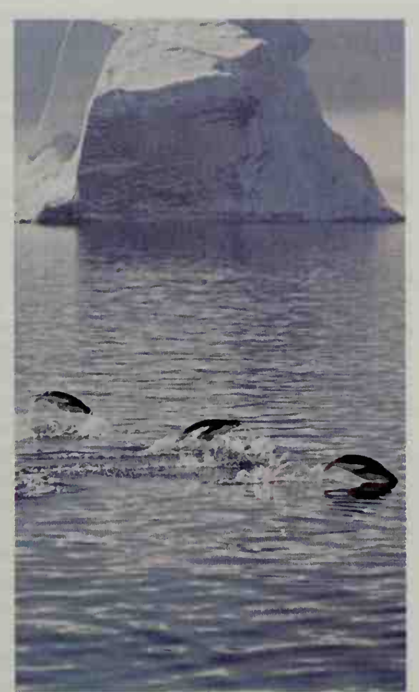
Penguins lost the ability to fly millions of years ago. As they began to spend most of their time in the water, their wings started to look more like flippers. This major change helped make penguins excellent swimmers. They "fly" underwater using the same motion as birds that fly in the air.

The body of a penguin is specially suited to living in the sea. Penguins are covered with short, thick feathers that form a waterproof coat. Their feathers are black or bluish-gray, except on their underside, where the feathers are white. Some penguin species have yellow or orange feathers on the head, neck, or breast. Thick layers of blubber keep the birds warm in cold water. For additional warmth, penguins that live where the weather is extremely cold have an extra layer of long, downy feathers below their waterproof feathers.

A penguin's beak can be black, red, bright purple, or orange. The feet are black, blue, or pink. Penguins use their feet to steer themselves when they are underwater. Some penguins have a crest of feathers on their head.

There are 17 *species* (kinds) of penguins. The largest is the *emperor penguin,* which stands about 4 feet (1.2 meters) tall and may weigh up to 100 pounds (45 kilograms). The emperor penguin ranks as one of the heaviest birds. The smallest penguin is the *little penguin,* sometimes called the *fairy penguin,* which stands about 1 foot (30 centimeters) tall and usually weighs about 3 pounds (1.4 kilograms). Most other species are $1\frac{1}{2}$ to 3 feet (45 to 90 centimeters) tall and weigh 5 to 15 pounds (2.3 to 6.8 kilograms).

Penguins can swim for many hours at about 8 miles (13 kilometers) per hour. In short bursts, they can reach three times that speed. Penguins swim below the surface, but they leap into the air for breath about once a minute. They can also dive much deeper than any other bird. Some species dive nearly 900 feet (275 meters) below the surface. The deepest divers can hold their breath for nearly 20 minutes.



The life of penguins. Penguins eat fish, squid, and *crustaceans,* which include crabs and shrimp. The birds use so much energy swimming that they must consume huge amounts of food. As a result, they live in waters that contain large populations of prey. Animals that feed on penguins include seals, sea lions, and killer whales.

All penguins in the wild live south of the equator. They are not found in northern areas because they will not cross into warm ocean water from the cold seas they prefer. The *Galapagos penguin* lives the farthest north. This bird inhabits the cold waters around the Galapagos Islands, which lie almost on the equator in the

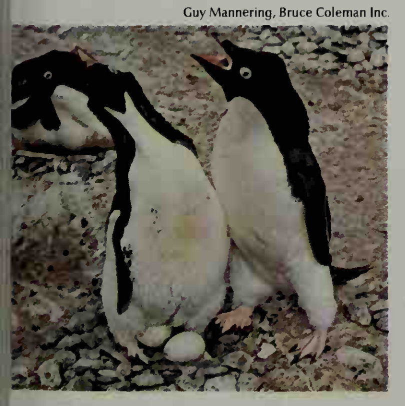
astern Pacific Ocean. Eight species of penguins make heir home among the islands near New Zealand and ustralia. Three species inhabit the coast of South merica, and one lives near southern Africa. Six species ve far south, in the icy waters near Antarctica.

Penguins seldom visit land except to raise their oung. They make their nests in enormous gatherings alled *colonies.* Most colonies occur on islands. Some e in coastal areas, but only where there are no land nammals that might eat the penguin chicks or eggs. A enguin colony can have thousands of members. The olonies are noisy because the birds often call to one



another with a braying sound like donkeys. Penguins recognize each other mostly by their voice.

Most penguins make their nests by digging shallow burrows under large rocks or bushes. Antarctic penguins build nests of pebbles on the ground because the frozen earth is too difficult to dig. The king penguin and emperor penguin build no nests at all. They keep their eggs or small chicks warm under a fold of their belly, holding them on the tops of their feet.

A pair of male and female penguins may nest together every year for many years. The female usually lays one or two eggs. Penguin eggs take from 30 to 65

days to hatch. Larger species take longer to hatch and to grow. Once laid, the egg must be *incubated* (kept at body temperature). Both parents take turns searching for food and caring for the eggs. The parent at the nest does not eat while the other parent is away, sometimes for a month at a time or longer.

When a chick hatches, the parents must guard it until it is strong enough to defend itself. It remains near the nest for the first 2 to 12 months of its life, depending on the species. The chick is covered by downy feathers that are slowly replaced by mature ones. It eats partially digested food fed to it by its parents. When young penguins are old enough, they leave the colony and learn to feed themselves at sea. They return to land only to *molt* (shed their feathers) and to *breed* (produce young). Penguins usually choose a mate and a nesting site close to where they were born. Though penguins sometimes travel thousands of miles or kilometers from their nesting place, they are able to return to their exact birthplace. Scientists believe penguins can navigate using the sun, stars, and geographical landmarks.

Some penguins kept in zoos have lived for more than 30 years. But in the wild, most species have a life span of about 20 years.

Conservation. Penguins are one of the oldest groups of birds. They have lived separately from land mammals, including human beings, for millions of years. Penguin populations are easily disturbed by human activity. For example, even a small amount of oil in the ocean is harmful to the birds. It robs their feathers of the ability to keep them warm. Also, commercial fishing in waters where penguins live makes it harder for them to find enough food. Because human activity has spread into areas where penguins live, some penguin species are in danger of dying out. David G. Ainley

Scientific classification. Penguins belong to the family Spheniscidae. The scientific name of the emperor penguin is *Aptenodytes forsteri*. The king penguin is *A. patagonica*. The little penguin is *Eudyptula minor*. The Galapagos penguin is *Spheniscus mendiculus*.

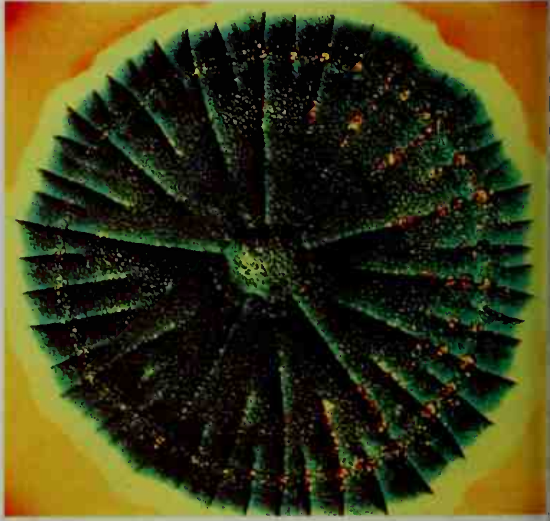
Penicillin is a powerful drug used to treat infections caused by bacteria. It was the first *antibiotic* (drug produced by microbes) used successfully to treat serious diseases in human beings. Sir Alexander Fleming, a British scientist, discovered penicillin in 1928. Various forms of the drug, called penicillins, have become widely available for medical use since the mid-1940's. Penicillins have played a major role in treating pneumonia, rheumatic fever, scarlet fever, and other diseases. The development of penicillins had a tremendous impact on medicine and encouraged research that led to the discovery of many other antibiotics.

Forms of penicillin. There are many kinds of penicillin. They all come from molds of the *genus* (scientific group) named *Penicillium* (PEHN *uh SIHL ee uhm*). Chemists isolate some natural penicillin substances by processing *Penicillium* molds in various ways. They produce other forms, called *semisynthetic penicillins,* by changing natural penicillin substances through chemical processes. *Penicillin G* is the most widely used natural penicillin. Commonly used semisynthetic penicillins are *ampicillin* (AM *puh SIHL ihn*), *amoxicillin* (*uh MAHK suh* SIHL *ihn*), *penicillin V*, and *nafcillin* (*NAF sihl ihn*). Semisynthetic penicillins called *extended spectrum* and *broad spectrum penicillins* are effective against many types of bacteria. Two examples of such penicillins are *ticarcillin* (TIHK *uhr SIHL ihn*) and *piperacillin* (PIHP *uhr uh SIHL ihn*).



How penicillins work. Penicillins kill bacteria by preventing the formation of the stiff cell walls bacteria need to survive. Human cells do not form stiff cell walls, and so they remain undamaged by penicillins.

Some penicillins can be taken *orally* (by mouth). But stomach acids destroy other penicillins taken orally before they reach the bloodstream. Doctors usually give such penicillins as injections.

Most people who take penicillins experience no side effects, though some people suffer allergic reactions. These reactions are usually minor, causing fever or rashes. However, life-threatening reactions involving shock and breathing difficulties occur in some patients. Patients allergic to one form of penicillin will likely react to all forms. As a result, doctors treat some patients allergic to penicillin with antibiotics called *cephalosporins* (SEHF *uh luh SPAWR ihnz*). These antibiotics are similar to penicillin and have been in use since the 1960's.

Early history. Fleming discovered penicillin in 1928 when he noticed mold growing in a lab dish containing common bacteria. He saw that the bacteria around the mold had died. In the 1930's, British researchers led by Howard Florey and Ernst Chain found a way to *extract* (pull out) and purify small amounts of penicillin. In 1941, a British policeman with blood poisoning became one of the first people treated with the drug. He began to recover but died because the hospital lacked an adequate supply of penicillin.

During the next several years, researchers found ways to produce large quantities of some penicillins. One of these, penicillin G, proved the most effective. But penicillin G was not effective when given orally, and it did not kill certain bacteria. In the late 1950's, chemists be-

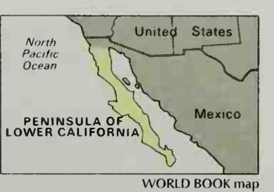
gan making semisynthetic penicillins to overcome these problems. Most semisynthetic penicillins have one or more properties not found in penicillin G. For example, penicillin V kills the same bacteria as penicillin G, but blood absorbs it better. Ampicillin and amoxicillin are effective against some kinds of bacteria that penicillin G cannot kill. Doctors use these drugs to treat urinary tract infections, and throat and ear infections in children.



Resistance. Since the 1950's, many bacteria have become resistant to penicillin. Resistant bacteria are unaffected by certain penicillins or other antibiotics. Resistance can occur when the genes of a bacterium change in a way that makes it unaffected by a certain antibiotic. The bacterium's offspring will also be unaffected by that drug. Bacteria can also become resistant by exchanging genetic material with other bacteria. One example of a kind of bacteria that often resists penicillin is *Streptococcus pneumoniae (STREHP tuh KAHK uhs noo MOH nee eye),* a cause of pneumonia. Most *Staphylococcus aureus (STAF uh luh KAHK uhs AW ree uhs)* bacteria, which cause skin and bloodstream infections, are penicillin resistant. Penicillins are now ineffective in treating a commonly sexually transmitted disease called *gonorrhea (GAHN uh REE uh).*

The widespread use of antibiotics to treat infections in human beings and livestock increases the number of resistant bacteria. Resistance to antibiotics is a growing threat to public health. Nelson M. Gantz

Peninsula, *puh NIHN suh luh,* is an area of land that is nearly surrounded by water. Peninsulas are usually long, narrow strips, but they also may span vast areas. Some peninsulas are joined to the mainland by a broad base. Others are connected by a narrow strip of land, called an *isthmus* (see **Isthmus**). Arabia, the largest peninsula, covers about 1,000,000 square miles (2,600,000 square kilometers). Anthony J. Lewis

Penis is an external male reproductive organ. In men and most other male mammals, both urine and a sperm-carrying fluid called *semen* leave the body through the penis. The penis is shaped somewhat like a finger. It hangs between the legs and is attached to the pelvic bones by connective tissues.

Thin, hairless skin covers the penis. Inside are three adjoining cylinders of spongy tissue that contains many blood vessels. These cylinders are bound together by a fibrous sheath. One of them encloses the *urethra,* a passageway for semen and urine. The urethra ends as an opening in the tip of the penis. The tip, called the *head* or *glans,* is slightly enlarged and has highly sensitive nerve endings. A fold of skin called the *foreskin* or *prepuce* covers the glans. In many males, the foreskin has been removed by a surgical procedure called *circumcision* (see **Circumcision**).

The penis is usually soft and limp. Sexual excitement increases the flow of blood to the organ, filling its tissues and making it stiff and erect. The stiffened penis, called an *erection,* enables the male to have sexual intercourse. In a sexually mature male, stimulation of the erect penis leads to *ejaculation,* the discharge of semen that accompanies sexual climax. After ejaculation, blood drainage returns the penis to its normal state.

Penn, John (1740-1788), a North Carolina delegate to the Continental Congress from 1775 to 1780, was a signer of the Declaration of Independence. When Penn was 21, he received a license to practice law. He practiced successfully for about 12 years in Virginia. In 1774, he moved to North Carolina, where he became a Revolutionary leader and served as a member of the provincial congress. He returned to his law practice after the Revolutionary War. Penn was born in Caroline County, Virginia. James H. Hutson

Penn, William (1644-1718), was a famous English Quaker who founded Pennsylvania. The Quakers, or Friends, were often treated harshly in England. They wanted the right to follow their religious beliefs without scorn or fear of violence. Penn, one of their leaders, persuaded King Charles II to let them set up a colony in America. This colony became the state of Pennsylvania.

Youthful rebel. Penn was born on Oct. 14, 1644, in London, the son of a naval officer later knighted as

Historical Society of Pennsylvania, Philadelphia

William Penn, an English Quaker, founded the colony of Pennsylvania in 1681. The above portrait of Penn was drawn in chalk about 1700 by Francis Place, an English artist.

Admiral Sir William Penn. The boy went to school in Essex. He entered Christ Church, Oxford University, in 1660. This was the year the Stuart family returned to the throne of England. Penn opposed the university rule that everyone must attend the Church of England. He believed in religious freedom and the right of individuals to worship as they pleased. Penn met with other rebellious students, outside the university, and was expelled from school. His father then sent Penn to France and Italy, hoping that the fashionable life there would make the boy forget his religious beliefs, or at least change them. Penn returned after two years of travel and study. The signs of his religious zeal were gone. His father, glad for this change, sent him to study law in London.

Penn went to Ireland in 1667 to manage his father's estates. There, he became acquainted with Thomas Loe, a Quaker preacher. Loe convinced him of the "truth" of the Quaker faith. Penn was then 22 years old. He chose to become a Quaker at a time when Quakers were scorned, ridiculed, imprisoned, and sometimes banished. His father was heartbroken.

Persecution. Penn was imprisoned several times for writing and preaching about Quakerism. He was first imprisoned in the Tower of London. After eight months, his father managed to have him released. During this imprisonment, Penn wrote *No Cross, No Crown* (1668), a piece explaining Quaker beliefs and practices.

In 1670, he was arrested at a Quaker meeting and accused of planning with another Quaker to start a riot. A jury found Penn not guilty of any crime. But the judge threatened to fine or imprison the jurors unless they changed their verdict. When they refused to do so, the jurors were in fact imprisoned. But on appeal, England's highest judges prohibited the penalizing of jurors. This action helped establish the independence of juries.

In 1677, Penn went to the Netherlands and Germany with George Fox and other Quaker leaders (see **Fox, George**). In these countries, Penn met other Quakers who were eager to settle in a free, new land. Some people in England also wanted to settle where they could worship in their own way without fear. Penn realized that the only hope for the Quakers was in America.

Founds Pennsylvania. Charles II owed Penn's father an unpaid debt of about $80,000. In 1680, Penn asked the king to repay the debt with wilderness land in America. On March 4, 1681, a charter was granted, giving Penn the territory west of the Delaware River between New York and Maryland. The charter also gave him almost unlimited ruling power over it. The king's council added *Penn* to the suggested name of *Sylvania,* making *Pennsylvania,* which means *Penn's Woods.* Penn drew settlers, including many Quakers, with promises of religious liberty and cheap land. Several thousand people came from England, Germany, the Netherlands, and Wales. Penn drew up a frame of government for his colony which greatly influenced later charters. It authorized an elected assembly and may even have influenced the Constitution of the United States.

In October 1682, Penn sailed up the Delaware River, and saw his colony for the first time. That same year, he made his first treaty with the Indians. His dealings with the Indians were so fair that they never attacked the colony. Penn returned to England in 1684 after the colony was well started. See **Pennsylvania** (History); **Philadelphia** (History).

Arrested again. In his drive for religious tolerance, Penn had become a close ally of King James II of England, a Roman Catholic. James granted pardons to Quakers and other religious prisoners. But in the Glorious Revolution of 1688, James was forced to give up the throne and flee abroad. His daughter Mary and her husband, Prince William of Orange, who were Protestants, became joint rulers of England in 1689. Penn was suspected of plotting the return of James, and was arrested several times. In 1692, his colony was placed under royal control. Penn wrote two of his greatest works in 1693. One was *An Essay Towards the Present and Future Peace of Europe,* a plan for a league of nations in Europe based on international justice. The other, *Some Fruits of Solitude,* described general principles for proper living. In 1694, Penn's colony was restored to him. That same year, Penn's wife, Gulielma Maria Springett Penn, died. They had married in 1672 and had eight children. In 1696, Penn married Hannah Callowhill, who was to bear him seven more children.

Penn returned to Pennsylvania in 1699. Problems had arisen in the colony over government, piracy, and illegal trade. Penn had some success solving these issues. He granted a new constitution, the Charter of Privileges, in 1701. This document created a *unicameral* (one-house) elected assembly with greater power. The provincial council was reduced from a legislative body to a small group of advisers to the governor. Efforts by the English government to place all proprietary colonies under royal control caused Penn to return to England in 1701. He never saw America again.

The government attempt to gain control failed. But

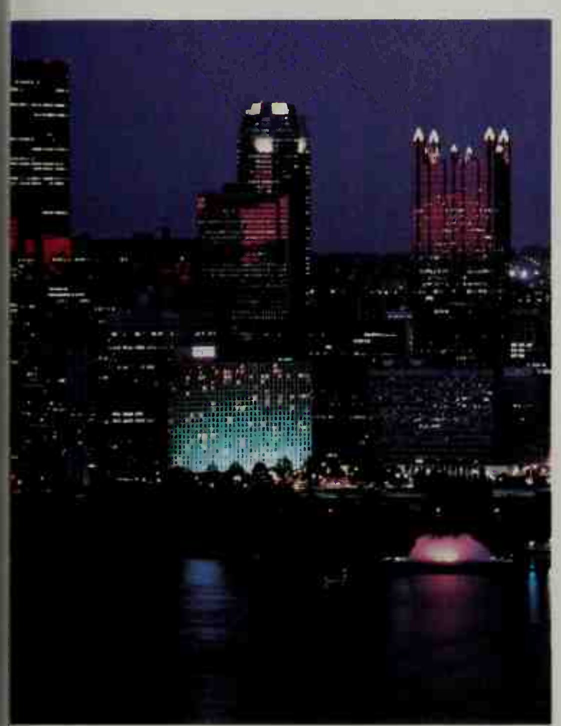
A scenic Lancaster County farm lies amid the rolling plains of Pennsylvania's Piedmont region. This area in the southeastern part of the state has some of the nation's richest farmland.

Pennsylvania *The Keystone State*

Pennsylvania is a leading manufacturing and industrial center of the United States. It also ranks as one of the nation's most historic states. It is one of four states officially called *commonwealths.* The other three are Kentucky, Massachusetts, and Virginia. Harrisburg is the state capital, and Philadelphia is the largest city.

Pennsylvania's chief manufacturing activities include the production of chemicals, electrical equipment, and processed foods. Service industries, such as banking, education, health care, and retail trade, also play a leading role in the state's economy.

Eastern Pennsylvania supplies all the *anthracite* (hard coal) that is produced in the United States. Mines in western Pennsylvania produce huge quantities of *bituminous* (soft) coal. Bituminous coal is used in generating electricity and in making coke, an important fuel used in the steel industry.



Philadelphia, in southeast Pennsylvania, is the state's leading manufacturing city. It is one of the nation's great cultural, educational, financial, and historical centers and also a chief port city. Pittsburgh, on the Ohio River in western Pennsylvania, is an important financial center. It is also a center of manufacturing. Hershey, in southeastern Pennsylvania, is the site of the world's largest chocolate and confectionery factory.

Most of Pennsylvania is made up of hills, plateaus, ridges, and valleys. The northwestern and southeastern corners of the state are low and flat. The lowest point in the state is sea level along the Delaware River. Mount Davis, in southern Pennsylvania, rises 3,213 feet (979 meters) above sea level and is the highest point in the state. Forests cover about three-fifths of Pennsylvania. Much of the state has rich farmland. The southeastern section has some of the richest soil in the United States. Crops prosper there. Poultry and cattle are also raised in the southeast. Dairy farming thrives in eastern Pennsylvania. The soil along Lake Erie in the northwest is good for growing fruits and vegetables.

Many tourists travel through the section of southeastern Pennsylvania in which the *Pennsylvania Dutch* people live. Most Pennsylvania Dutch people are descended from German immigrants. These immigrants were called *Dutch* because the word *Deutsch,* which means *German,* was misinterpreted. The Pennsylvania Dutch are known for fine cooking and for the colorful designs and decorations on many of their buildings and belongings. Some Pennsylvania Dutch groups, including the Amish and Mennonites, are called the *Plain People.* Many Plain People live and dress as their ancestors did and do not believe in using electricity, automobiles, telephones, or modern machinery.

The ice cream soda was invented in Philadelphia in 1874. Robert M. Green created it at the semicentennial celebration of the Franklin Institute. According to legend, Green usually made a drink from sweet cream, syrup, and carbonated water. At the celebration, he ran out of sweet cream and substituted ice cream. The creation was so popular that his profits rose from $6 to $600 per day.

1794 The nation's first major hard-surfaced road, between Philadelphia and Lancaster, was opened.

1859 Edwin Drake drilled the nation's first commercially successful oil well, near Titusville.

1940 The first section of the Pennsylvania Turnpike was opened.

1987 Pennsylvania marked the bicentennial of its statehood.

People

Population. The 2000 United States census reported that Pennsylvania had 12,281,054 people. The population had increased about 3 $\frac{1}{2}$ percent over the 1990 census figure, 11,881,643. According to the 2000 United States census, Pennsylvania ranks 6th in population among the 50 states.

Over four-fifths of Pennsylvania's people live in metropolitan areas (see **Metropolitan area**). The largest of these areas include Philadelphia, Pittsburgh, Allentown-Bethlehem-Easton, Harrisburg-Lebanon-Carlisle, and Scranton-Wilkes-Barre-Hazelton. For a complete list and populations of these metropolitan areas, see the *Index* to the political map of Pennsylvania.

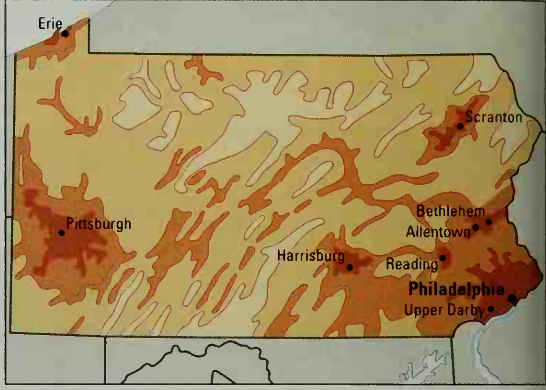
Philadelphia is Pennsylvania's largest city, and one of the largest cities in the United States. Other large cities, in order of population, are Pittsburgh, Allentown, Erie, Reading, Scranton, and Bethlehem.

Pennsylvania's largest population groups include people of German, Irish, Italian, and English descent. About 10 percent of the people are African Americans. Other large groups include people of Polish, Slovak, and Dutch descent.

Several groups of Pennsylvanians are the descendants of Germans who came to the area in the 1600's and 1700's. They are often called *Pennsylvania Dutch*. Some of them still speak a mixture of German and English. Others speak English, but with an accent. The Pennsylvania Dutch include such religious groups as the Amish, Dunkers, and Mennonites. See **Pennsylvania Dutch**.

Schools. Most of the early teaching in Pennsylvania was controlled by churches. During the 1640's, Swedish Lutheran ministers taught in Tinicum, near what is now Essington. Pennsylvania's first colonial constitution, adopted in 1682, provided that children should know how to read and write by the age of 12. The Friends' public school, founded in Philadelphia by Quakers in 1689, still exists as the William Penn Charter School.

The state Constitution of 1790 stated that the legislature should provide schools for the children of poor parents. In 1834, the legislature passed the Free School Act. This act provided for the establishment of school districts throughout the state.



Today, each city, township, and borough in Pennsylvania has, or is part of, a school district. The state board of education, with 17 members appointed by the governor and 4 members of the legislature, establishes policies for the state's public school system. Pennsylvania's secretary of education administers the policies. A state law requires children from age 8 through 16 to attend school. For the number of students and teachers in Pennsylvania, see **Education** (table).

Libraries. Benjamin Franklin and some of his friends founded the Library Company of Philadelphia in 1731. It was the first subscription library in the American Colonies. Members contributed money to buy books for it and could then use the books without charge. In 1876, more than a hundred librarians gathered in Philadelphia for the first meeting of the American Library Association. In the late 1800's, industrialist Andrew Carnegie donated

Population density

Most of Pennsylvania's people live in the Philadelphia and Pittsburgh metropolitan areas. In mountainous central Pennsylvania, the population is scattered among valleys.

ıoney to build public libraries in five communities.

Today, the state has thousands of public, school, aca-emic, and special libraries. The Free Library of Philadel-hia is the largest library. Other large libraries include ittsburgh's Carnegie Library, the University of Pennsyl-ania library, and the State Library of Pennsylvania.

Museums. The Pennsylvania Academy of the Fine rts in Philadelphia, founded in 1805, operates the na-on's oldest art museum. The Academy of Natural Sci-nces of Philadelphia is the oldest institution of natural ciences in the United States. The Academy of Natural ciences was founded in 1812.

The nation's first institute of applied sciences and me-anical arts, the Franklin Institute, opened in Philadel-hia in 1824. It houses the Fels Planetarium. The State luseum and the State Archives are in Harrisburg.

Other museums in Pennsylvania include the Mercer luseum of the Bucks County Historical Society in oylestown; Drake Well Museum in Titusville; Hershey luseum in Hershey; the Railroad Museum of Pennsyl-ania in Strasburg; the Landis Valley Museum in Lancas-r; and the Philadelphia Museum of Art and Rodin Museum, both in Philadelphia. Carnegie Museums of Pittsburgh includes the Carnegie Museum of Art, the Carnegie Museum of Natural History, the Carnegie Science Center, and the Andy Warhol Museum.

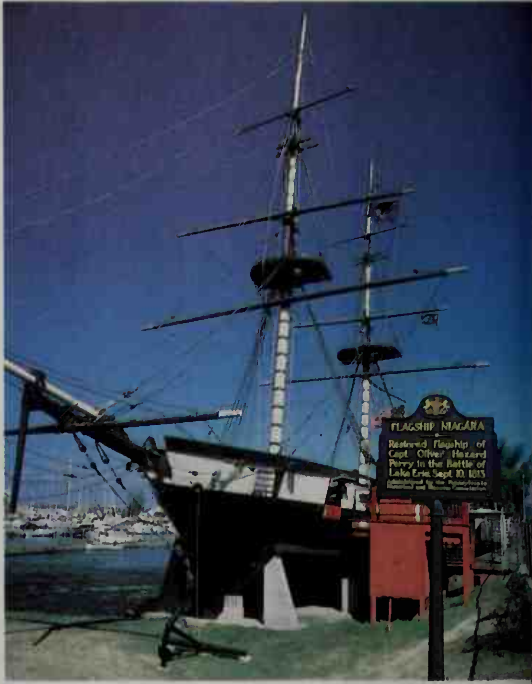
Visitor's guide



Pennsylvania's wide variety of activities and diverse experiences attract thousands of visitors each year. Vacationers can enjoy such activities as hiking, biking, fishing, white-water rafting, hunting, and skiing. They may also experience the outdoors at any of the 116 state parks scattered throughout Pennsylvania. The state is also home to more than 1,000 museums and hundreds of historical sites that help illustrate the state's rich history. Thrill seekers may want to visit one of the 20 amusement parks in the state.

One of Pennsylvania's most popular annual events is the Mummers' Parade, held on New Year's Day in Philadelphia. People celebrate the New Year by dressing in costumes and marching through the streets.

Places to visit

Following are brief descriptions of some of Pennsylvania's many interesting places to visit:

Ephrata Cloisters, in Ephrata, is a restored religious community built by German Seventh-Day Baptists in 1732. During the summer months, the famous Ephrata choir sings and a historical pageant is presented.

Fallingwater, near Uniontown, is one of American architect Frank Lloyd Wright's most acclaimed works. The home, which was completed in the 1930's, was built over a natural waterfall.

Flagship ***Niagara,*** restored in Erie, is the ship of Oliver Hazard Perry, who defeated the British navy on the Great Lakes during the War of 1812.

Hawk Mountain Bird Sanctuary, in the Kittatinny Mountains, is one of the world's few refuges for birds of prey.

Philadelphia, the birthplace of the United States, was the nation's capital during most of the Revolutionary War. Visitors can see many historic sites at Independence National Historical Park. The U.S. Mint conducts four tours daily. See **Philadelphia** (The city).

Pittsburgh offers visitors many attractions that reflect the city's rich history and industrial heritage. Tourists can visit Point State Park, which was once the site of Fort Dusquesne and Fort Pitt. Mount Washington, a hill that overlooks downtown Pittsburgh, features spectacular views of the city.

Steamtown National Historic Site, in Scranton, is the only site in the National Park System dedicated to steam railroading. The park's history museum includes displays on early railroads, life on the railroad, and the relationship between railroads, business, and government.

Parklands in Pennsylvania are among the state's most interesting tourist attractions. Gettysburg National Military Park was the scene of the historic Battle of Gettysburg during the Civil War. There, on Nov. 19, 1863, Abraham Lincoln delivered his famous Gettysburg Address. Independence National Historical Park in Philadelphia features such fascinating landmarks as Independence Hall, Congress Hall, and many other historic places. For more information about these and other parklands that the National Park Service administers in Pennsylvania, see the map and tables in the *World Book* article on **National Park System.**

National forest. Allegheny National Forest is located in northwestern Pennsylvania. It covers 510,536 acres (206,607 hectares).

State parks and forests. Pennsylvania has 116 state parks, 5 historical parks, 44 natural areas, 13 wild areas, and about 30 state forest picnic areas. For information on the state parks of Pennsylvania, write to Pennsylvania Department of Environmental Resources, Bureau of State Parks, Market Street State Office Building, Harrisburg, PA 17105.

New Year's Day Mummers' Parade in Philadelphia

Land regions. During the Pleistocene Epoch, which ended about 11,500 years ago, glaciers spread into what is now northern Pennsylvania. They formed some of the state's striking natural features.

Pennsylvania has seven main land regions: (1) the Erie Lowland, (2) the Appalachian Plateau, (3) the Appalachian Ridge and Valley Region, (4) the Blue Ridge, (5) the Piedmont, (6) the New England Upland, and (7) the Atlantic Coastal Plain.

The Erie Lowland covers parts of Pennsylvania and New York. It is a narrow strip in the northwestern corner of Pennsylvania, on Lake Erie's shores. The region's flatland was once part of the lake bed. Vegetables and fruits, especially grapes, thrive in its sandy soil.

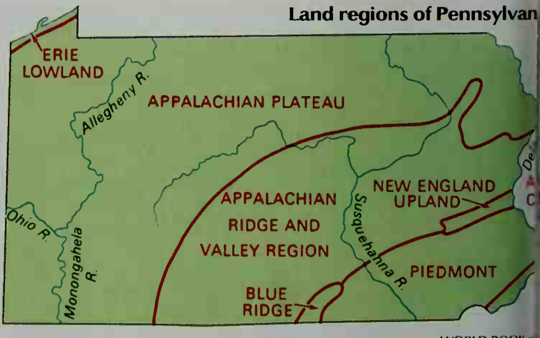
The Appalachian Plateau extends from New York to Alabama. In Pennsylvania, it is also called the *Allegheny Plateau.* It covers the entire northern and western portions of Pennsylvania, except for the narrow Erie Lowland region. The Appalachian Plateau consists of deep, narrow valleys and broad-topped plateaulike *divides* (land ridges from which rivers flow in opposite directions). Glacial rocks and boulders dot the northern part of the region. Plateaus rise 2,000 feet (610 meters) or more in the north-central section, and slope gradually to the east, west, and southwest. The Allegheny Mountains, at the plateau's eastern edge, extend from north-central Pennsylvania to West Virginia and Virginia. Chestnut Ridge and Laurel Hill, in southwestern Pennsylvania, form some of the higher and more rugged parts of the region. Mount Davis, the state's highest point, rises 3,213 feet (979 meters) in Somerset County near the southern boundary. The western Appalachian Plateau has many coal, gas, and oil fields. The Pocono Mountains are in the northeastern part of the plateau.

The Appalachian Ridge and Valley Region extends from New York to Alabama. In Pennsylvania, it forms a wide strip of land that curves south and east of the Appalachian Plateau. The area where the ridge and valley region and the plateau meet is called the *Allegheny Front.* It forms a large physical barrier.

An area called the Great Valley sweeps along the southern and eastern boundary of Pennsylvania's ridge and valley region. The Great Valley is divided into the Cumberland, Lebanon, and Lehigh valleys. All these valleys have fertile farmland. North and west of the Great Valley, the region consists of a series of long, parallel ridges and valleys that curve from southwest to northeast. The ridges include Blue, Jacks, and Tuscarora mountains, which belong to the Appalachian Mountain system. The ridges consist of folded layers of *sedimentary rock* (rock formed from deposits laid down by ancient rivers and lakes). Erosion has worn down the softer rock layers, forming the valleys. The Delaware Water Gap opens through the Kittatinny Mountains along the Pennsylvania-New Jersey boundary. Hard-coal fields and slate formations are in the eastern part of the region.

The Blue Ridge, named for the Blue Ridge Mountains stretches from southern Pennsylvania to Georgia. In Pennsylvania, it forms a narrow, finger-shaped region at the state's south-central border. Beautiful South Mountain, scenic Buchanan Valley, and part of Gettysburg National Military Park are in this region.

The Piedmont extends from New Jersey to Alabama. In Pennsylvania, it covers most of the southeastern part of the state. The region has rolling plains, and low hills with irregular ridges and fertile valleys. The Pennsylvania Dutch areas of Lancaster and York counties have some of the richest farmland in the United States.



The New England Upland extends from Pennsylvania to Maine. In Pennsylvania, it forms a narrow rectangular ridge in the eastern section. The ridge crosses portions

The Delaware Water Gap is a popular resort area along the Pennsylvania-New Jersey border. The Delaware River cut the gap through the Kittatinny Mountains millions of years ago.

The Appalachian Plateau, also called the Allegheny Plateau, covers most of northern and western Pennsylvania. This rugged region consists of broad ridges and deep, narrow valleys.

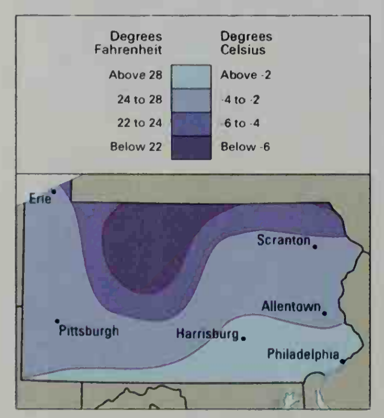
of Berks, Bucks, Lehigh, and Northampton counties.

The Atlantic Coastal Plain stretches from New York to southern Florida. In Pennsylvania, it is a narrow strip of land that crosses the southeastern corner. The region is low, level, and fertile. It drops to sea level along the Delaware River. Philadelphia is near the region's center.

Rivers, waterfalls, and lakes. Eastern and central Pennsylvania are drained by the Delaware, Juniata, Lehigh, Schuylkill, and Susquehanna rivers. The Ohio River system drains western Pennsylvania. The Ohio begins where the Allegheny and Monongahela rivers meet at Pittsburgh. The waters that form or feed the Ohio River include the Allegheny, Monongahela, Beaver, Conemaugh, and Youghiogheny rivers. The Ohio flows to the Gulf of Mexico by way of the Mississippi River.

Some of the most spectacular waterfalls in the Eastern United States plunge over cliffs in the Pocono Mountains. Falls include Bushkill, Raymondskill, and Winona falls. Other waterfalls in the state are Beaver, Buttermilk, Dingmans, and Silver Thread.

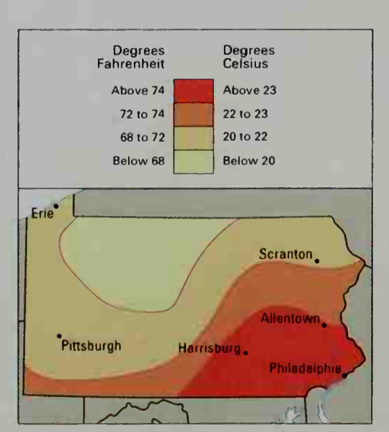
Lake Conneaut is the largest natural lake entirely within Pennsylvania. It covers about 1 $\frac{1}{2}$ square miles (3.9 square kilometers) in the northwestern section. The largest body of water in the state is artificially created Raystown Lake. It covers 13 square miles (34 square kilometers) in southwestern Pennsylvania. Pymatuning Reservoir covers almost 26 square miles (67 square kilometers). It extends into Ohio. Many glacial lakes dot the northeastern Appalachian Plateau. Lake Erie touches the northwestern corner of Pennsylvania.



Plant and animal life. Forests cover about three-fifths of Pennsylvania. Mixtures of hardwood and softwood trees are found in the north and on the higher ridges in the south. They consist mainly of beeches, birches, hemlocks, maples, and pines. Hardwoods, including hickories, oaks, and walnuts, grow chiefly in the lowland sections of the southeast and southwest. These trees may also be found in some of the northern valleys of the Appalachian Ridge and Valley Region. Other common trees include the ash, aspen, basswood, black cherry, sycamore, and yellow-poplar.

Rhododendrons, wild azaleas, wild berries, wild ginger, and wintergreen grow throughout Pennsylvania. Shrubbery of mountain laurel, the state flower, spreads over much of the countryside. Colorful clusters of bouncing Bet, hound's-tongue, milkweed, sundew, and viper's bugloss brighten the riverbanks. Greenbriers and ferns grow in the western valleys. Common spring flowers include the anemone, bloodroot, dog-tooth violet, hepatica, and wild honeysuckle.

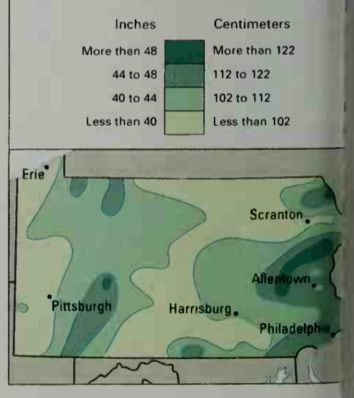
Animal life includes deer, moles, muskrats, opossums, rabbits, raccoons, skunks, snakes, and squirrels. Black bears, the state's most prized game animals, roam the mountains and wooded areas of northern Pennsylvania. The ruffed grouse, the state bird, feeds along woodland streams. Wild turkeys live in some parts of the state. Other common game birds include gray partridges and ring-necked pheasants. Fishes in the lakes, rivers, and streams include bass, brown trout, carp, chubs, and pickerels. Pennsylvania has some of the best-known trout streams for fly-fishing in the eastern United States.



Average January temperatures

Pennsylvania has a cold winter climate. The north has the lowest temperatures. The southeast has the mildest winters.

Average July temperatures



The southeastern part of Pennsylvania has the warmest summers. Temperatures increasingly decline to the northwest.

Average yearly precipitation

Precipitation varies widely throughout the state. The central and western sections of Pennsylvania are the driest.

Climate. Pennsylvania has a moist climate with cold winters and warm summers. Northern and western Pennsylvania are generally colder than the southern and eastern parts. January temperatures average 26 °F (−3.3 °C) in the north, 27 °F (−2.8 °C) in the Erie Lowland, and 34 °F (1 °C) in the southeast. Average July temperatures range from 70 °F (21 °C) in the northwest to 75 °F (24 °C) in the southwest and 77 °F (25 °C) in the southeast. Pennsylvania's record low temperature, −42 °F (−41 °C), occurred in Smethport in McKean County on Jan. 5, 1904. Phoenixville, in southeastern Pennsylvania, had the record high, 111 °F (44 °C), on July 10, 1936.

The state's yearly *precipitation* (rain, melted snow, and other forms of moisture) averages about 41 inches (104 centimeters). The northwest has 34 to 44 inches (86 to 112 centimeters) a year. The southeast has 42 to 47 inches (107 to 119 centimeters). Snowfall averages from 20 inches (51 centimeters) in southeastern Pennsylvania to 90 inches (230 centimeters) in the northwestern part of the state.

Economy

Until the 1970's, Pennsylvania's economy relied heavily n manufacturing steel and machinery. Factories in most arts of the state made these products. Pennsylvania still anks among the leading producers of steel and machin-y, but these items are now much less important to the conomy. The leading manufactured goods in the state e now chemicals, food products, and computer com-onents. The Philadelphia and Pittsburgh areas are ennsylvania's leading manufacturing centers. Other im-ortant manufacturing cities in Pennsylvania include Al-ntown, Bethlehem, Erie, Harrisburg, Lancaster, Read-g, Scranton, Wilkes-Barre, Williamsport, and York.

Despite Pennsylvania's importance as a manufacturing ate, service industries make up the largest part of the conomy. Such activities as banking, health care, and re-il trade have grown rapidly in importance since the 70's. Service industries provide jobs for about three-urths of Pennsylvania's workers. Several of the service dustries benefit from tourism. Tourism is especially nportant in Philadelphia, along Lake Erie, in the Pocono ountains, and in the Pennsylvania Dutch area.

Agriculture and mining each contribute only a small ortion of Pennsylvania's gross state product. Milk is the ate's leading agricultural product. Dairy farms can be und throughout the state. Coal is Pennsylvania's most portant mined product. Western Pennsylvania pro-ices large amounts of bituminous coal from both sur-e and underground mines. Mines in the eastern part the state provide all of the nation's *anthracite* (hard al).

Natural resources of Pennsylvania include rich soils, eat mineral wealth, good water supplies, and plentiful nber

Soil. Pennsylvania has many kinds of soil. Much of the edmont, the New England Upland, and the Atlantic astal Plain regions are covered with well-drained, ay-brown to reddish-brown soils. These are some of e most fertile soils in the eastern United States. Rich ale and limestone soils cover the valleys of the Ap-achian Ridge and Valley Region. Stony soils cover much of the hard, sandstone-capped ridges. Gravelly and sandy loams, formed by glacial lake deposits, cover the Erie Lowland in extreme northwestern Pennsylvania. Infertile sandstone and shale soils cover much of the Appalachian Plateau.

Minerals. Large deposits of anthracite occur in Lackawanna, Luzerne, Schuylkill, and other counties in eastern Pennsylvania. The western part of the state has huge deposits of *bituminous* (soft) coal. Deposits of dolomite, limestone, sandstone, and shale are also common. Most of the western counties of the state have natural gas and petroleum fields. Deposits of iron ore lie near Reading. Other mined products found in Pennsylvania include clays; mica; peat; slate; and *tripoli,* a kind of silica.

Service industries taken together account for the largest portion of Pennsylvania's gross state product.

Most of the service industries are located in the Philadelphia and Pittsburgh metropolitan areas.

Community, business, and personal services form Pennsylvania's leading service industry in terms of the gross state product. This industry employs more people than any other industry in the state. It includes businesses such as hotels, professional sports franchises, private health care, and engineering and law firms. Philadelphia is home to some of the nation's leading law firms. Pittsburgh has many engineering firms.

Finance, insurance, and real estate form the second-ranking service industry in Pennsylvania in terms of the gross state product. The Philadelphia and Pittsburgh areas are important national financial centers. Several large holding companies and banks have headquarters located in the two areas. Philadelphia has a major stock exchange. Real estate is important to Pennsylvania because of the large amounts of money involved in the buying and selling of properties.

Ranking next among Pennsylvania's service industries is wholesale and retail trade. The wholesale trade of automobiles, coal, groceries, industrial machinery, and petroleum is especially important. The Port of Philadelphia handles large quantities of imported petroleum. Major types of retail trade establishments include automobile dealerships, department stores, grocery stores, and restaurants.

Government ranks fourth among the service industries. Government services include the operation of public schools and hospitals, and military activities.

Transportation, communication, and utilities form the state's fifth-ranking service industry. More information about transportation and communication appears later in this section.

Manufacturing. Goods manufactured in Pennsylvania have a *value added by manufacture* of about $90 billion yearly. Value added by manufacture represents the increase in value of raw materials after they become finished products. Pennsylvania is among the top manufacturing states. Many types of manufactured products

nake important contributions to the state's economy.

Chemicals are Pennsylvania's leading manufactured ›roduct in terms of value added by manufacture. Phar- naceuticals are the most important part of the state's :hemical industry. One of world's largest producers of ›rescription drugs is based in Philadelphia. A leading .spirin producer has operations in Pittsburgh. Other hemicals manufactured in Pennsylvania include paint, ›etrochemicals, and synthetic resins.

Processed foods and beverages rank second among 'ennsylvania's manufactured goods. The leading prod- cts include beer, bread and cakes, chocolate and co- oa products, cookies and crackers, and sausages and ›repared meats. Pennsylvania is a leading food-process- ıg state. It leads the United States in mushroom can- ing, and ranks among the leaders in the manufacture of :e cream, potato chips, and pretzels. Hershey Foods, /hich was founded in Pennsylvania, operates the largest hocolate and cocoa factory in the world. The Philadel- hia area is the state's principal food-processing center.

Ranking third among the state's manufactured prod- cts is computer and electronic equipment. The leading roducts in this sector include semiconductors and oth- r electronic components, scientific instruments for in- ustry, and communications equipment. The suburban reas of Philadelphia and Pittsburgh are the leading re- ions for the manufacture of electronic equipment.

Fabricated metal products rank next among the state's ıanufactured products. Sheet metal, metal plate, and ther structural metal products are the chief fabricated ıetal products. Industrial machinery is the fifth-ranking ıanufactured product. The Philadelphia and Pittsburgh 'eas are the main machinery manufacturing centers.

Other manufactured products of Pennsylvania include rimary metals, transportation equipment, paper prod- :ts, and printed materials. Steel is, by far, the leading rimary metal produced in the state. Types of trans- ›rtation equipment made in Pennsylvania include air- 'aft, motor vehicles, and railroad cars. Paper mills oper- e in many counties throughout the state. Commercial 'int shops and newspaper, book, and magazine pub- ;hers turn out most of Pennsylvania's printed materials.

Pennsylvania ranks among the leading states in making clothing and textiles, glass products, plastics products, and refined petroleum. The Philadelphia and Allentown-Easton areas are the major producers of clothing and textiles. One of the world's largest glass companies is based in Pittsburgh. The state's many plastics products include plastic bags, pipes, and bottles. Marcus Hook and Philadelphia have large oil refineries.

Agriculture. Farmland covers about a third of Pennsylvania's land area. The state has about 60,000 farms.

Livestock and livestock products earn about two-thirds of Pennsylvania's total farm income. Milk is the state's leading agricultural product. Pennsylvania is among the leading states in milk production. Dairy farming flourishes in eastern Pennsylvania. Poultry products and beef cattle rank next in value among the state's livestock products. The southeastern part of the state has many poultry farms, and Pennsylvania ranks among the leading egg-producing states. Cattle graze on the rolling hills of the southwest and in valleys along the Susquehanna River in the southeastern part of the state. Pennsylvania farmers also raise hogs and turkeys.

Crops account for about one-third of the state's farm income. Mushrooms are the leading crop, and the state ranks first in mushroom production. Most of the mushrooms are grown in southeastern Pennsylvania in special houses that are damp and cool. Corn and hay are the chief field crops. The Piedmont region leads in corn and hay production. Much of the corn and hay is used to feed beef and dairy cattle. Other important field crops include oats, potatoes, soybeans, tomatoes, and wheat.

Greenhouse and nursery products are another important source of agricultural income in Pennsylvania. They include cut flowers, house plants, and ornamental shrubs. The leading fruit crops are apples and peaches. They are grown in southern Pennsylvania. Cherries, grapes, and strawberries are also grown in the state.

Mining. Pennsylvania ranks among the leading states in coal production. The state's eastern counties mine about 5 million tons (4 $\frac{1}{2}$ million metric tons) of anthracite yearly. No other state mines anthracite. The western counties and other parts of Pennsylvania mine

about 75 million tons (68 million metric tons) of bituminous coal a year. This type of coal is used to make coke and generate electric power.

Among Pennsylvania's other mined products, limestone and natural gas are most important. Limestone is used to make cement and roadbeds. Western Pennsylvania provides almost all of the state's natural gas. Pennsylvania's other mined products include sand and gravel, and petroleum.

Electric power. About 60 percent of Pennsylvania's electric power is produced by plants that burn coal. Nuclear power plants provide about 35 percent of the power. Plants that burn petroleum produce most of the rest. Pennsylvania sells some of its power to nearby states.

Beginning in 1999, Pennsylvania's electric utilities were *deregulated.* Deregulation allows customers to choose their electricity provider. Competition among utilities should result in lower electricity costs.

Transportation. Pennsylvania has been a transportation leader since colonial times. One famous early road, Queen's Road, linked Philadelphia and Chester. It was completed in 1706. The Old York Road was built between Philadelphia and New York City in the early 1700's. The nation's first major hard-surfaced road was opened between Philadelphia and Lancaster in 1794. The Pennsylvania Railroad was chartered in 1846. The first section of the Pennsylvania Turnpike, between Middlesex and Irwin, was completed in 1940. The turnpike was later extended east to New Jersey, west to Ohio, and north from Philadelphia to Scranton. East-west and north-south interstate highways were built in the 1960's and 1970's. Carlisle is a major trucking center.

Philadelphia and Pittsburgh both have major international airports. Harrisburg also has an international air terminal.

Many Pennsylvania communities are served by water transportation. Pittsburgh is the center of the state's inland waterway system. From Pittsburgh, boats can travel about 980 miles (1,580 kilometers) on the Ohio River, 130 miles (210 kilometers) on the Monongahela, and 70 miles (110 kilometers) on the Allegheny. Oceangoing ships can travel up the Delaware River as far as Philadelphia, and beyond to Morrisville. Philadelphia ranks as one of the leading port cities in the United States. Pittsburgh and Erie are also important port cities.

Communication. Pennsylvania's first newspaper, the *American Weekly Mercury,* was established in Philadelphia in 1719. It was the fourth newspaper published in the American Colonies, and the first published outside of Boston. Benjamin Franklin of Philadelphia published the *Pennsylvania Gazette* from 1729 until 1766, and *Poor Richard's Almanac* for the years from 1733 through 1758. In 1741, Andrew Bradford established America's first magazine, in Philadelphia. Bradford called his publication *The American Magazine, or A Monthly View of the Political State of the British Colonies.*

In 1919, Frank Conrad, an engineer of the Westinghouse Electric Corporation, set up a broadcasting station, 8XK, in his Wilkinsburg home. The following year, Conrad and some of the other Westinghouse engineers established radio station KDKA in Pittsburgh. It began broadcasting on Nov. 2, 1920. KDKA and Detroit's WWJ were the first regular commercial radio stations in the United States. Pennsylvania's first television station began broadcasting in Philadelphia in 1941. The station broadcasts as KYW-TV.

Pennsylvania has about 380 newspapers, of which about 85 are dailies. Leading newspapers include the *Philadelphia Inquirer,* the *Philadelphia Daily News,* the *Pittsburgh Post-Gazette,* and *The Morning Call* of Allentown. The *Philadelphia Tribune* is one of the nation's most widely circulated African American newspapers. More than 750 periodicals are published in Pennsylvania. The state has about 370 radio stations and 45 television stations. Cable television systems and Internet providers serve many communities.

Government

Constitution. Pennsylvania's Constitution was adopted in 1968. The state had adopted earlier constitutions in 1776, 1790, 1838, and 1874.

Constitutional *amendments* (changes) may be proposed by the state legislature. An amendment must be approved by a majority of both houses. It must then be approved in a similar manner by the next legislature. Finally, it must be approved by a majority of the people voting on the amendment in the next election.

Amendments also can be proposed by a constitutional convention. Before a constitutional convention can meet, it must be approved by a majority of both legislative houses and by the voters in a regular election.

Executive. Pennsylvania's governor is elected by the people to a four-year term. The governor may not serve more than two terms in a row.

The governor appoints the secretary of the commonwealth (secretary of state), adjutant general, and several other administrative officials. The people of Pennsylvania elect the lieutenant governor, the attorney general, the state treasurer, and the auditor general. Like the governor, these elected officials serve four-year terms. They may serve an unlimited number of terms, but not more than two terms in a row.

Legislature, called the General Assembly, consists of a 50-member Senate and a 203-member House of Representatives. Voters in each of the state's 50 senatorial districts elect one senator. Voters in each of the 203 representative districts elect one representative. Senators serve four-year terms, and representatives serve two-year terms. Regular sessions begin on the first Tuesday in January and last until all business is completed or until November 30 of an even-numbered year, whichever occurs first. The governor may call special sessions of the General Assembly. By law, the General Assembly must be *reapportioned* (redivided) after each United States census to provide equal representation based on population.

Courts. Pennsylvania's highest court is the state Supreme Court. It has seven justices, who are elected to 10-year terms. The justices may be *retained* (approved for an additional 10-year term in a noncontested election). The justice with the longest continuous time in office serves as the chief justice.

Pennsylvania's Superior Court and the Commonwealth Court are intermediate appellate courts. The Supreme Court, Superior Court, and Commonwealth Court meet at fixed times each year in Harrisburg, Pittsburgh, and Philadelphia. The Superior Court has 15 active judges, and the Commonwealth Court has nine. These judges are elected to 10-year terms and may be retained.

The trial courts of Pennsylvania are divided into 60 judicial districts, each with a Court of Common Pleas. Other courts include the Minor Judiciary, the Philadelphia Municipal Court, the Philadelphia Traffic Court, and the Pittsburgh Magistrates Court.

Local government. Pennsylvania has four kinds of local government units: (1) counties, (2) townships, (3) cities, and (4) boroughs. Sixty-two of the state's 67 counties are governed by a board of three commissioners, elected to four-year terms. Philadelphia is a consolidated city and county. It has a mayor and a 17-member council, who govern both the city and the county. Delaware County is governed by five council members, who serve four-year terms. Erie, Lehigh, and Northampton counties elect executives, who serve four-year terms.

Most rural and suburban communities operate as townships. Most of the larger townships are called first-class townships. They are governed by boards made up of at least five commissioners who are elected to four-year terms. Other townships, especially the smaller ones, are called second-class townships. These townships are governed by boards made up of three supervisors elected to six-year terms.

Pennsylvania has 56 cities. Many of these cities, including Philadelphia and Pittsburgh, use the mayor-council form of government. A few cities use the council-manager form. Many of Pennsylvania's smaller cities use the commission form of government.

*The office of governor was created by the Pennsylvania Constitution of 1790. That year, Thomas Mifflin became the first governor. Before 1790, Mifflin and those who served ahead of him held office as president of the state Supreme Executive Council.
†Democratic-Republican

Pennsylvania is one of the few states that has *boroughs*. These are incorporated units of municipal government that generally are smaller than cities. Most of Pennsylvania's boroughs are governed by a mayor and by councils elected to four-year terms.

Units of local government can adopt *home rule* (self-government) to the extent of selecting or changing their form of government. They can also merge with other units.

Revenue. Taxes account for more than half of the state government's *general revenue* (income). Most of the rest comes from federal grants and other U.S. government programs. A personal income tax and a general sales tax are the major sources of tax revenue. Other important sources of tax revenue include taxes on corporate income, corporation licenses, motor fuels, public utilities, and motor vehicle licenses.

Politics. Pennsylvania favored Republican candidates in most state and national elections between the American Civil War and the 1930's. Democrats have gained strength since the early 1930's, especially in the larger cities. Since 1932, Democratic and Republican presidential candidates have won the state's electoral votes about the same number of times. For Pennsylvania's electoral votes and voting record in presidential elections, see **Electoral College** (table).

History

Indian days. Indians probably lived in the Pennsylvania region thousands of years before Europeans came. Early European explorers found Algonquian and Iroquoian Indians there. The Algonquian tribes included the Conoy, Delaware, Nanticoke, and Shawnee. The Iroquoian tribe, the Susquehannock, lived along the Susquehanna River.

Exploration and settlement. In 1609, the English explorer Henry Hudson sailed into Delaware Bay. He was trying to find a trade route to the Far East for the Dutch East India Company. Hudson soon left the Pennsylvania region, but his reports led the Dutch to send other explorers. In 1615, a Dutch explorer, Cornelius Hendricksen, sailed up the Delaware River to what is now Philadelphia.

The Swedes made the first permanent settlements in the Pennsylvania region. In 1643, they made Tinicum Island, near what is now Philadelphia, the capital of their colony of New Sweden. In 1655, Dutch troops led by Peter Stuyvesant came from New Netherland and captured New Sweden (see **Stuyvesant, Peter**). The Dutch held the Pennsylvania region until 1664, when the English captured it.

The English Duke of York controlled the Pennsylvania region until 1681. That year, King Charles II of England granted the region to William Penn in payment of a debt to Penn's father. Penn wanted to name the region New Wales. But a Welsh member of England's Privy Council objected to the name. So Penn decided to call the region *Sylvania,* which means *woods*. King Charles added *Penn* to the name in honor of Penn's father, an English admiral.

Colonial days. William Penn, a Quaker, wanted his fellow Quakers to have freedom of worship in Pennsylvania. He also desired religious freedom for people of other faiths. Penn wanted Pennsylvanians to enjoy personal and property rights, and to have self-government. Penn came to Pennsylvania in 1682. As governor, he wrote and brought with him the colony's first constitution, called the Frame of Government. It provided for a deputy governor and an elected legislature. The legislature consisted of a provincial council (upper house) and a general assembly (lower house).

Penn made a treaty of friendship with the Indians shortly after he arrived in the Pennsylvania region. He paid the Indians for most of the land King Charles had given him, although he did not have to do so. According to legend, Penn and Tamenend, the chief of the Delaware Indians, exchanged wampum belts under the now famous Shackamaxon elm near Philadelphia.

The general assembly did not fully approve of the Frame of Government. In 1683, the legislature drafted and adopted a second Frame of Government. This constitution gave the people more voice in the government by reducing the powers of rich landowners.

Penn went to England in 1684, leaving control of the government in the hands of a deputy governor. Troubles developed during Penn's absence. Members of the general assembly resented the provincial council's power to originate laws. The assembly rejected or delayed action on much legislation that had originated in the council. When Penn learned about the trouble, he placed most of the powers of government in the hands of the provincial council. But the council failed to restore order. In 1688, Penn appointed another deputy governor.

In 1688, King James II, a close friend of Penn's, was overthrown. King James's daughter Mary and her husband, Prince William of Orange, became joint rulers of England in 1689. William and Mary did not trust Penn because of his friendship with King James. In 1692, they deprived Penn of his right to govern Pennsylvania. The royal governor of New York was made governor of Pennsylvania as well. In 1693, Penn convinced William and Mary of his loyalty. They restored him as governor of Pennsylvania in 1694.

Troubles still existed in the Pennsylvania legislature. In 1696, Penn's deputy governor, William Markham, suggested some constitutional changes. He wanted both legislative houses to have the power to originate laws. But this change still did not satisfy many members of the legislature.

Penn returned to Pennsylvania in 1699. In 1701, he granted a new constitution, called the Charter of Privileges. This constitution made the general assembly the only lawmaking body in the colony. It gave the provincial council an advisory role. It also gave greater control of the government to the people.

Penn returned to England again in 1701 and died there in 1718. Penn's family governed Pennsylvania until the Revolutionary War began in 1775.

Colonial wars. From the late 1600's to the middle 1700's, the English colonists fought several wars against the French colonists and France's Indian allies. In the

ylvania in 1754, they fought for control of the Ohio
:iver region and interior of the continent. One of the
nost brutal battles of the war took place in 1755. The
rench and Indians ambushed General Edward Brad-
lock's troops on the banks of the Monongahela River
ear present-day Pittsburgh. Most of Braddock's sol-
liers were killed or wounded. Fighting continued in
'ennsylvania until 1758, when the French withdrew from
ne colony as British General John Forbes led a large
rmy through the region. The war ended in 1763, with a
ritish victory.

Pontiac, an Ottawa chief, led an uprising against the
ritish later in 1763. He lost the Battle of Bushy Run, near
resent-day Greensburg. Pennsylvania bought land from
ne Indians in the Fort Stanwix Treaty of 1768. This treaty
ettled most of the colony's Indian troubles.

The Revolutionary War. In the mid-1700's, Britain
ound itself in debt. To raise money, Britain imposed
ew taxes and trade restrictions on its colonies in Amer-
:a. The colonies united to oppose these measures. Co-
onial leaders met to discuss how to resist the British re-
trictions. The First Continental Congress met in Phila-
elphia on Sept. 5, 1774. The Congress voted to stop all
ade with Britain.

hiladelphia in December 1776. Congress moved to Bal-
more for safety. But the British were turned away, and
ongress returned to Philadelphia in March 1777. British
oops marched into Pennsylvania in September 1777.
They defeated General George Washington's forces in the Battle of Brandywine on September 11. The British then marched toward Philadelphia. Congress moved first to Lancaster, and then to York. On September 20 and 21, the British killed many American soldiers in the *Paoli Massacre,* outside Philadelphia. On September 26, the British marched across the Schuylkill River and captured Philadelphia. Washington led a sudden attack against the British on October 4, hoping to force them out of the city. But the attack failed. Washington led his

troops to Whitemarsh, and then to Valley Forge where they spent a difficult winter and spring.

In spite of their victories in Pennsylvania, the war was beginning to go badly for the British. In June 1778, they withdrew from Philadelphia. The Continental Congress returned to the city. While in York, the Congress had adopted the Articles of Confederation. Pennsylvania approved the Articles on July 9, 1778.

Meanwhile, settlers in the Wyoming Valley, in present-day Luzerne County, were in danger of attack by British and Indians. In the summer of 1778, the settlers fled to a fort near what is now Wilkes-Barre. That July, an army of about 800 British soldiers and Indians attacked the fort, killing about two-thirds of the settlers. The incident became known as the *Wyoming Valley Massacre.*

The Constitutional Convention met in Philadelphia from May to September 1787. Pennsylvania became the second state to *ratify* (approve) the United States Constitution, on Dec. 12, 1787. Philadelphia served as the nation's capital from 1790 until 1800, when the government was moved to Washington, D.C.

Industrial growth. As early as 1750, Pennsylvania had become a leader in the colonial iron and grain milling industries. After the Revolutionary War, Pennsylvania became a center of the nation's industrial growth. In 1787, John Fitch demonstrated the first workable steamboat in the United States. It sailed on the Delaware River, near Philadelphia. In 1811, a steamboat built by Robert Fulton was launched at Pittsburgh. It became the first to travel on the Ohio and Mississippi rivers. The Schuylkill Canal connected Philadelphia and Reading in 1825. In 1826, the state began building the Pennsylvania Canal System. The main line of the system, a series of connecting canals and railroads, linked Philadelphia with Pittsburgh by 1834.

The Battle of Germantown took place north of Philadelphia after General George Washington led his troops in a surprise attack on the British army on Oct. 4, 1777.

By 1840, the use of anthracite as a fuel led to improvements in Pennsylvania's iron industry. By the 1850's, many railroads carried coal from northeast Pennsylvania to Philadelphia. In 1859, Edwin Drake drilled the nation's first commercially successful oil well, near Titusville. By 1860, Philadelphia was a leading producer of textile, leather, and iron goods. Pittsburgh, a center of iron and glass production, was known as the *Gateway to the West.*

The Civil War. Many Pennsylvanians were among the leaders of the *abolitionist* (antislavery) movement in the United States. Some Pennsylvanians helped slaves escape to freedom through a system called the underground railroad (see **Underground railroad**). During the Civil War (1861-1865), Pennsylvania gave strong support to the Union. The state sent 340,000 troops to the Union Army. Only New York sent more troops.

Several raids and one major Civil War battle took place in Pennsylvania. The Confederate cavalry generals Jeb Stuart and Wade Hampton led raids through the Cumberland Valley in October 1862. In June 1863, General Robert E. Lee led his powerful Confederate Army of about 75,000 men into Pennsylvania. On July 1, Union forces under General George G. Meade met the Confederates at Gettysburg, in southern Pennsylvania. The three-day battle that followed was one of the bloodiest in history. It broke the strength of the Confederacy, and Lee retreated to Virginia. On Nov. 19, 1863, President Abraham Lincoln dedicated part of the Gettysburg battlefield as a cemetery for those who had died there. He delivered his famous Gettysburg Address at the ceremonies.

Confederate General John McCausland invaded Pennsylvania in July 1864. His forces attacked and burned Chambersburg, and then they quickly left the state.

Progress as a state. Pennsylvania prospered after the Civil War. Existing agricultural, lumber, and mining industries expanded, and many new industries developed. Pennsylvania became a leading producer of oil, cement, electrical equipment, and aluminum. Pittsburgh became the largest steel producer in the United States. Thousands of immigrants came to the state, and cities and towns grew.

But industrial growth brought labor problems. Workers in many industries formed unions and demanded higher wages. Railroad workers went on strike in 1877. Riots broke out, and strikers destroyed valuable railroad property. In Pittsburgh, a violent clash between strikers and soldiers of the state militia left several people dead.

In 1892, the Carnegie Steel Company reduced wages at its plant in Homestead, and the workers went on strike. In a fight between strikers and guards hired by the steel company, several people were killed.

In 1889, Johnstown, in southern Pennsylvania, suffered one of the state's worst disasters—a flood that killed more than 2,000 people (see **Johnstown**).

Continued industrial growth. In the early 1900's, for the first time, more than half the people of Pennsylvania lived in cities and towns. Pennsylvania mined a large share of the coal in the United States. The state also produced most of the nation's coke and about 60 percent of

its steel. Many large industrial companies made their headquarters in Pennsylvania.

Manufacturing and mining in Pennsylvania achieved even greater growth after the United States entered World War I in 1917. In addition to production of military goods, the state contributed about 8 percent of the personnel of the U.S. armed forces.

The Great Depression. During the Great Depression of the 1930's, hundreds of thousands of Pennsylvanians lost their jobs. The state passed welfare laws in cooperation with the federal government to help ease the hardship. In addition, Pennsylvania set up programs of highway building, reforestation, and conservation, and passed laws that included a minimum wage for women and children, and a 44-hour workweek.

In 1936, floodwaters swept across many parts of the state. Pittsburgh and Johnstown were particularly hard hit. The floods killed more than 100 people and caused over $40 million in damage.

Urban renewal. Pennsylvania's economy recovered during World War II (1939-1945). The industries of the state produced huge quantities of cement, clothing, coal, petroleum, ships, steel, and weapons for the armed services.

Pennsylvania began to modernize in many fields during the mid-1900's. The first section of the Pennsylvania Turnpike opened in 1940. By 1956, the highway was completed across the state. During the 1940's, Pennsylvania cities began urban redevelopment programs. Pittsburgh rebuilt nearly all its downtown area, and Philadelphia modernized portions of its central city. In the 1950's, the state built hundreds of new schools and reorganized its welfare programs.

Economic decline. During the 1950's, serious economic problems developed. Pennsylvania's giant steel industry was hurt by competition from other products, and by a 116-day strike in 1959. The state's coal production fell sharply as the demand for anthracite and bituminous coal declined in the United States. Many mines closed, putting miners out of work. Thousands of Pennsylvanians also lost their jobs because of a decline in railroading. Thousands of other Pennsylvanians became jobless as textile mills were automated or moved to the South, where costs were lower.

In 1967, Pennsylvania called its first constitutional convention in 94 years. In 1968, voters approved a new constitution to replace the one that had been adopted in 1874.

In the 1970's and 1980's, Pennsylvania, especially its older cities, faced several difficulties. Many traditional manufacturing industries shut down or reduced the number of employees. The steel industry continued to decline because of foreign competition and other problems. Many more coal mines closed. Thousands of workers, especially steelworkers, lost their jobs, and many small industrial towns faced hard times.

The state's population growth leveled off. The average age of the population increased because many young adults left the state. The central cities of metropolitan areas faced such issues as high unemployment and loss of people to growing suburbs. Revenues of local governments declined.

These problems challenged Pennsylvanians to attract new industries, stabilize the older cities, and work to maintain such public structures as roads and bridges. In 1971, the state legislature approved an individual income tax to help pay state operating expenses. It also established a state-operated lottery which supported social programs for the elderly.

The Three Mile Island nuclear power plant near Harrisburg was the site of a nuclear accident in 1979. President Jimmy Carter, *center,* inspected the plant shortly after the accident.

In 1972, Tropical Storm Agnes swept across the Eastern United States. The storm and floods that it caused resulted in 55 deaths and about $3 billion in damage in Pennsylvania. Wilkes-Barre and Harrisburg suffered the most damage among Pennsylvania cities.

In 1979, an accident at the Three Mile Island nuclear power plant located near Harrisburg threatened the release of deadly levels of radiation into the area. Scientists and technicians prevented a major disaster from occurring. The accident raised concerns about the safety of nuclear power production.

Recovery. In the 1990's, Pennsylvania was able to achieve a balanced and healthy economy. With the support of the state government, the state's strong educational, financial, medical, and cultural institutions led the shift from older manufacturing activities to an economy based on service industries.

Although Pennsylvania remained a leading steelmaking state, service industries transformed the metropolitan areas of Philadelphia, Pittsburgh, Allentown, and other Pennsylvania cities. Workers found employment in such areas as medical research, health care, and interstate banking and in industries using new technology.

Pennsylvania worked to preserve and restore many historic sites and buildings, especially in Philadelphia and Pittsburgh. The state also established several *heritage parks.* These areas highlight the history of various regions and the role each played in the state's industrial development. These activities created thousands of jobs and attracted millions of dollars in new investment. They also contributed to the growth of the state's tourism industry. Edward K. Muller and William C. University of Pennsylvania

The University of Pennsylvania is one of the oldest U.S. universities. Its campus has buildings that date from the 1700's.

Pennsylvania, University of, in Philadelphia, is one of the oldest institutions of higher learning in the United States. It is a privately controlled, coeducational school, but it receives a small portion of its operating budget from the state. Benjamin Franklin was one of the school's founders. It started in 1740 as a Charity School, became an Academy in 1749, and was named the College and Academy of Philadelphia in 1756. In 1791, it adopted its present name and became the first school in the United States to be called a university.

The university offers undergraduate courses in engineering; finance and commerce; liberal arts and sciences; and nursing. The Wharton School was the first collegiate business school in the United States. The graduate and professional schools offer courses in architecture and fine arts; arts and sciences; communications; dental medicine; education; law; medicine; social work; and veterinary medicine. The Wharton School and the nursing and engineering schools also have graduate divisions. Other academic divisions are the College of General Studies and the Wharton Evening School. The University of Pennsylvania also has several noted research institutes.

The university library includes special collections on medieval history, Shakespeare, Sanskrit manuscripts, Italian Renaissance, and Walt Whitman. The Union Library Catalogue lists 6 million volumes owned by libraries in the Philadelphia area.

The university museum has noted collections of Babylonian material, Chinese sculpture, and Middle American, Pacific, and African art. It conducts archaeological expeditions each year.

Pennsylvania Dutch refers to the people who came to Pennsylvania in the late 1600's and the 1700's from the German Rhineland, and their descendants. Some of these immigrants came from the German part of Switzerland, and others were French Huguenots. Only a few of them came from the Netherlands. The Pennsylvania Dutch were called *Dutch* because the word *Deutsch,* which means *German,* was misinterpreted.

These settlers came to Pennsylvania to escape war and religious persecution in the Rhineland. They settled mainly in southeastern Pennsylvania. By 1790, the Pennsylvania Dutch made up one-third of Pennsylvania's population.

The Pennsylvania Dutch valued their agricultural life and worked their fields industriously. The community often worked together to provide assistance to individuals in farm and social matters. These qualities helped the Pennsylvania Dutch prosper as farmers.

Most of the original Pennsylvania Dutch belonged to the Lutheran or German Reformed churches. They were called "the church people." Others belonged to various *sects* (religious groups) that grew out of *pietism,* a religious movement that opposed formal religious practices. These sects included the Amish and Mennonites. These two groups were noted for their plain dress and distrust of formal church practices. Today the Amish and Mennonites are called "the plain people," and live mainly in Lancaster County. Another early group, the Moravians, founded Bethlehem, Pennsylvania, and worked to convert American Indians to Christianity. See **Amish; Mennonites; Moravian Church.**

Pennsylvania Dutch folk art includes this colorful hand-drawn birth and baptismal certificate from the early 1800's.

Pennsylvania Dutch artisans became well known for their clocks, glassware, pewterware, and pottery. They also invented the Conestoga wagon and the Pennsylvania rifle. Many Pennsylvania Dutch still maintain their dialect and unique customs. Their distinctive art style is known for its colorful decorative motifs. Many Pennsylvania Dutch buildings are decorated with colorful designs called *hex signs.* Such hex signs as a star within a circle were once intended to protect against evil spirits, but they now serve mainly as decoration.

The people's love of music has resulted in beautiful church music, especially choirs such as the famed Bach choir. Characteristic dishes include *sauerkraut un schpeck* (sauerkraut and pork), *smearcase* (cottage cheese), and *schnitz un knepp* (dried apples and dumplings).

Pennsylvania State University is a coeducational land-grant institution that offers advanced education at more than 20 locations in Pennsylvania. The university, popularly known as Penn State, grants associate's, bachelor's, master's, and doctor's degrees.

Penn State is a major research university with programs in agricultural science, architecture, business, communications, earth and mineral sciences, and education. Additional programs include engineering, food science, health and human development, law, liberal arts, medicine, and physical and life sciences.

Penn State's main campus is University Park, in University Park, Pennsylvania. Many courses of study are available at University Park, including business, engineering, food science, liberal arts, and physical and life sciences. Penn State also has a network of colleges that grant associate's degrees. Most of these colleges also offer bachelor's degrees in a few specialized areas. The Pennsylvania College of Technology, in Williamsport, offers technical and vocational associate's degrees.

Penn State provides a wide variety of graduate programs at University Park and several other sites. The College of Medicine at the Milton S. Hershey Medical Center, in Hershey, offers degrees in medicine and other health sciences. Students can earn law degrees at Dickinson School of Law, in Carlisle.

Pennsylvania Turnpike is a 470-mile (755-kilometer) toll superhighway. It was the first successful American toll highway of any great length built for all types of motor vehicles. The turnpike's main line runs for 360 miles (580 kilometers) across Pennsylvania, from Ohio to New Jersey. The Northeastern Extension runs for 110 miles (180 kilometers) from a point near Norristown to an area north of Scranton. About 300,000 vehicles enter the turnpike system each day. The total mileage for all vehicles traveling on the turnpike in one year is about 4 $\frac{1}{4}$ billion miles (7 billion kilometers).

The turnpike opened in 1940. At that time, it spanned 160 miles (260 kilometers) from Irwin (near Pittsburgh) to Middlesex (near Carlisle).

Penny is the name used to describe various coins that are used in the United Kingdom, the United States, and other countries. The U.S. penny is a cent (see Cent). For many years, there were 240 British *pence* (pennies) in a pound. But in 1971, the United Kingdom switched to a decimal money system. In this system, 100 *pence* are equal to a pound. The penny was stamped with the symbol of a cross until about 1500, during the reign of Henry VII. At that time, the coin was designed so that it could easily be broken into four equal parts. It was used in halves as a *halfpenny* (pronounced *HAY puh nee*) and in fourths as a *farthing*. The old penny was abbreviated *d*, but today's penny is abbreviated *p*. For the price of the pound in United States dollars, see Money (table).

Scientific classification. Pennyroyals belong to the mint family, Lamiaceae or Labiatae.

Pennyweight is a unit of measure in the troy system of weights. It is used to weigh gold, silver, platinum, coins, and most jewels. The pennyweight was once the weight of a silver penny. Today it is standardized as one twentieth of a troy ounce, or 24 grains (1.6 grams).

Penobscot River, *puh NAHB skaht,* is the longest waterway in Maine. It rises near the Canadian border and flows eastward through forests (see Maine [physical map]). The river forms Chesuncook and Pemadumcook lakes. It then flows south for the rest of its 350 miles (563

kilometers) to empty into Penobscot Bay, on the Atlantic Ocean. Ocean vessels can sail up the river to Bangor, 60 miles (97 kilometers) from the sea. The name *Penobscot* comes from the Algonquian Indian words for *rocky river.*

Pensacola (pop. 56,255; met. area pop. 412,153) is Florida's largest deepwater seaport. It lies on Pensacola Bay in northwestern Florida. For the city's location, see **Florida** (political map). Its chief industries include chemical plants, fertilizer, fishing, furniture and boat making, and pulp and paper mills. The University of West Florida is in Pensacola. The area is the site of the Pensacola Naval Air Station (see **Pensacola Naval Air Station**).

Diego Maldonado, one of explorer Hernando de Soto's captains, reached Pensacola Bay, probably in 1540. In 1559, Spanish adventurer Tristan de Luna founded a settlement that lasted two years. Spain reoccupied Pensacola in 1698, when Spanish military leader Don Andres d'Arriola built a fort where the city now stands. Pensacola has a council-manager government. It is the seat of Escambia County. Peter O. Muller

Pensacola Dam is a federal flood-control and electric-power project on the Neosho River near Pensacola, Oklahoma. It is a multiple-arch, hollow-buttress dam with 51 arches and an 861-foot (262-meter) spillway. The dam is 145 feet (44 meters) high and 6,500 feet (1,980 meters) long at the top. It has a capacity of 2 million acre-feet (2.5 billion cubic meters) of water. The dam was completed in 1940. Larry W. Mays

Pensacola Naval Air Station, Florida, serves as the headquarters of the Chief of Naval Education and Training, a command that directs and controls all education and training for the United States Navy. Flight training for most Navy aviators begins at the station, which covers 11,386 acres (4,608 hectares) and lies 9 miles (14 kilometers) west of Pensacola. Major activities there include the Naval Air Technical Training Center and the Naval Operational Medicine Institute. The Naval Aviation Museum is also there. The Pensacola Naval Air Station was set up in 1914 on the site of an old naval shipyard. It reached a peak of activity in World War II (1939-1945), when 28,000 aviators trained there. W. W. Reid

Pension is a form of income that workers or their spouses receive after the workers retire, become disabled, or die. Pension plans benefit people who have had careers in private industry; in a nation's armed forces; or in national, state, and local governments. Many individuals who are self-employed or whose employers do not provide a pension establish their own pension plans.

About half the privately employed people in the United States, and nearly all United States government employees, are covered by some type of employer-sponsored pension plan. In addition, a government program commonly known as *social security* provides pension benefits to most United States workers after they retire. Workers in other countries also are covered by pension systems. This article discusses pension plans in the United States.

Most federal pensions are financed by contributions made by both employees and the employer. Most private group pension plans are funded by the employer only. Many people collect benefits from more than one pension plan.

Federal pension plans

The U.S. government administers four major types of pension plans: (1) social security, (2) railroad pensions, (3) military pensions, and (4) federal civilian pensions.

Social security is the largest retirement income pro-

gram in the country. The Social Security Administration, a government agency, runs the program. Employees pay part of their salaries to social security through the Federal Insurance Contributions Act (FICA) payroll tax. Employers contribute the same amounts paid by their employees. Most self-employed workers also pay part of their earnings to the program. Eligible people who retire at age 65 or older may get full social security benefits for the rest of their lives. Those retiring between 62 and 65 receive reduced benefits. For example, at age 62 people are eligible for 80 percent of their full benefits.

The social security program was established in 1935. Since then, the number of people receiving benefits has increased steadily. Benefits are raised each year to reflect increases in the cost of living. However, most people who receive social security must supplement it with income from other sources.

Railroad pensions provide retirement income for railroad workers. They are the only type of private industry pension managed by a government agency. The agency that manages them is the Railroad Retirement Board. Employee and worker contributions are supplemented by government revenues. Railroad workers qualify for a pension after 10 years of service. Retirees who are 65 or older, or are 62 or older and have worked at least 30 years, receive full benefits. The current railroad pension system was established in 1936.

Military pensions have provided retirement income for disabled veterans since the Revolutionary War (1775-1783) and for retired veterans since the early 1800's. The Uniformed Services Retirement System includes all military pension programs. It is funded by federal revenues.

Military personnel who have served a minimum of 20 years can retire at any age and receive benefits. Retirees receive pensions equal to 40 percent of their active-duty base pay if they retire after 20 years of service. Benefits reach a maximum of three-quarters of their active-duty base pay after 30 years of service.

Federal civilian pensions provide income for retired government employees other than military personnel. Many federal workers are covered by the Civil Service Retirement System (CSRS), which is funded by employees and the government. Workers receive full benefits if they retire at age 62 with at least 5 years of service; at age 60 with at least 20 years of service; or at age 55 with at least 30 years of service. In addition, many CSRS retirees qualify for social security benefits.

Federal employees hired during or after January 1987 are covered by the Federal Employees' Retirement System (FERS), which was established in 1986. The FERS also includes some employees formerly covered by the CSRS. The FERS provides benefits from social security, a federal retirement plan, and a thrift savings plan. The FERS retirement plan generally pays lower benefits than does the CSRS. The government contributes to the FERS thrift plan and matches a certain percentage of contributions made by employees to that plan.

Private pension plans

Many companies provide some type of pension program for their employees. In most programs, the benefits depend on an employee's age, years of service, and average salary. Federal law requires that all pension plans offer *vested pension rights* to workers who have completed a certain number of years of service. Most employees become fully vested after five years or less of service. Employees with vested rights are guaranteed pension benefits after retirement even if they leave the firm before they retire. However, almost no pension plans provide cost-of-living increases.

There are four main kinds of private pension programs. These programs include (1) trust-fund plans, (2) group annuity plans, (3) profit-sharing plans, and (4) thrift, or savings, plans.

Trust-fund plans pay benefits from a trust managed by a bank or other financial institution. Money paid to the pension funds is invested in stocks, bonds, and other sources of income. Most of the money is paid by the employer. Many employers who participate in trust-fund plans must pay premiums to a federal agency called the Pension Benefit Guaranty Corporation to insure worker benefits against inadequate funding.

Group annuity plans cover all participants with an insurance policy financed either by the employer alone or by both the employer and the employees. The policy guarantees that each worker will receive a monthly *annuity* (payment) after retiring. Life insurance firms manage most group annuity plans.

Profit-sharing plans are funded by employers, largely from a portion of their annual profits. People may be paid in monthly installments or with one lump sum.

Thrift, or savings, plans allow employees to make contributions for retirement. In most thrift plans, the employer matches a certain percentage of each employee's contributions. Companies typically match 50 percent of an employee's contributions up to a certain maximum amount. In most cases, an employee may contribute amounts above the maximum matched amount. One common type of company thrift plan is a *401 (k) plan.* Under this plan, all or part of the contributions come from pretax income, and taxes are deferred until money is withdrawn. Withdrawals or loans from such an account are permitted up to a set limit and only under certain conditions. If the employee exceeds the limit or does not meet the conditions, a federal penalty tax must be paid. Many employers provide a thrift plan in addition to another type of pension plan.

Individual pension plans

Many people put part of their income into an individual pension program. The two chief types of individual programs are *individual retirement accounts* and *Keogh plans.*

Individual retirement accounts are special savings accounts administered by such financial institutions as banks, savings and loan associations, and insurance companies. The money in an individual retirement account (IRA) earns interest that is automatically added to the account. In a traditional IRA, people who do not have private pension plans, or who earn less than a certain amount, may deposit a certain sum into the account each year without having to pay income tax on the deposited money until it is withdrawn. Others may make deposits but must pay tax on the money they deposit, at the time it is earned. The interest earned on any funds in a traditional IRA is not taxed until withdrawn.

In general, if an individual withdraws previously untaxed money from the account before reaching the age

of 59 $\frac{1}{2}$, a federal penalty tax must be paid. This rule does not apply when the money is withdrawn to pay for certain college expenses or to finance the purchase of a first home. At the age of 70 $\frac{1}{2}$, a person must withdraw all the funds from the account or start making periodic withdrawals.

In a type of IRA known as a Roth IRA, the money deposited in the account is subject to federal income tax at the time it is earned. But the government does not tax interest earned on the account.

Keogh plans may be set up only by people who are self-employed or who own all or part of an unincorporated business. Like IRA's, Keogh accounts are handled by banks and other financial institutions, and the money is not taxed until it is withdrawn.

History

In 1875, a transport firm called the American Express Company offered the first U.S. private pension plan. In 1880, railroads became the first major industry to provide a pension plan, and other industries soon established their own plans. Labor unions created pension funds for their members during the early 1900's. In 1935, Congress established the social security system.

In 1974, Congress passed the Employee Retirement Income Security Act (ERISA). This act set standards for private pension plans. Since the 1980's, the proportion of workers covered by private pensions has declined. Many companies have begun putting more emphasis on thrift plans instead. James H. Schulz

Pentagon is a polygon having five sides. It is called *equilateral* if all sides have the same length and *equiangular* if all its angles are equal. Like all polygons, except a triangle, a pentagon may be equilateral without being equiangular. Or it may be equiangular without being equilateral. A pentagon is *regular* if all the sides and interior angles are equal. Each angle equals 108° and may be inscribed in a circle. A pentagon may be circumscribed around a circle by drawing tangents to the circle at the vertices of a regular inscribed pentagon. See also **Polygon.**

Pentagon Building is one of the world's largest office buildings. It is the headquarters of the Department of Defense of the United States government. The building lies on the west bank of the Potomac River in Arlington, Virginia, across from Washington, D.C.

Built in the form of a *pentagon,* or five-sided figure, the building has five concentric rings connected by 10 spokelike corridors. It has five floors, a mezzanine, and a basement. The building covers 29 acres (12 hectares) and has about 3,706,000 square feet (344,300 square meters) of office and other space. The outermost wall of the concrete structure is faced with Indiana limestone. The building is surrounded by 200 acres (81 hectares) of lawn and terraces. Adjacent parking areas cover 67 acres (27 hectares). The lagoon at the building's river entrance was formed by excavation and juncture with the river.

Department of Defense

The Pentagon Building is one of the largest office buildings in the world. The five-sided structure stands across the Potomac River from Washington, D.C.

About 24,000 people work in the building. Most of them work for the departments of the Army, Navy, or Air Force, or the Office of the Secretary of Defense. About half of them are civilians.

The Pentagon Building has one of the world's largest private telephone systems and the largest pneumatic tube system. Pneumatic tubes transport letters and other such materials by means of air pressure. The building also has many shops, several cafeterias and restaurants, a radio and television station, a bank, a medical dispensary, a post office, and a heliport.

Army engineers began building the Pentagon in September 1941 and completed it by January 1943. It was built to house the scattered offices of the War Department under one roof. The building cost $83 million.

On Sept. 11, 2001, the Pentagon Building was damaged in the worst terrorist attack in U.S. history. Terrorists in a hijacked commercial jetliner crashed the plane into the Pentagon, cutting a gash in one side of the building and setting it on fire. Two other hijacked planes crashed into the two towers of the World Trade Center in New York City. A fourth hijacked plane crashed in Pennsylvania. Thousands of people died as a result of the attacks. Pentameter. See **Meter** (poetry).

Pentateuch, *PEHN tuh took,* consists of the first five books of the Bible. They are, in order, the books of Genesis, Exodus, Leviticus, Numbers, and Deuteronomy. The term comes from two Greek words that mean *five books* or *five scrolls.* According to tradition, the books were written by the Israelite leader Moses based on revelations from God. The Pentateuch is often called the Five

Books of Moses or the Torah (Law) of Moses.

The Pentateuch presents a continuous story from the Creation to the death of Moses and the preparation of the Israelites to enter Canaan. The story is told in three sections, sometimes called the *prehistory* or *primeval history,* the *protohistory,* and the *history.* The prehistory (Genesis 1-11) deals with the universal themes of the Creation and the beginning of human existence on earth. The protohistory (Genesis 12-50) presents the stories of several ancestors of the Israelites, notably Abraham, Isaac, Jacob, and Joseph. The historical portion, beginning with Exodus, describes the early history of Israel as a nation. The conclusion in Deuteronomy is presented as Moses's final address to his people and a kind of historical summary of the Pentateuch.

The Pentateuch is the oldest part of the Bible, though scholars do not know the precise date of composition. The earliest materials may precede its final form by more than 1,000 years. Modern archaeological discoveries suggest that some of the oldest stories in Genesis may date back to the 2000's B.C. Carol L. Meyers

Pentathlon, Modern, *pehn TATH lahn,* is an athletic competition for men and women that tests skill in pistol shooting, fencing, swimming, horseback riding, and running. Competitors participate in all five events, receiving a point score for each performance. The athlete with the highest score wins. The modern pentathlon can be held in both individual and team categories. It differs from the pentathlon, which consists of five track and field events.

The modern pentathlon is held in one day in both the Summer Olympic Games and in world championships. The first event is shooting an air pistol. Next is fencing with an epee sword. The third event is freestyle swimming, in which the athletes swim a 200-meter race. The fourth event is horseback riding over a course 350 to 450 meters (1,150 to 1,475 feet) long with 12 obstacles. The final event is a 3,000-meter cross-country race. Michael Takaha

Pentecost, *PEHN tuh kawst,* is the feast that marks the end of the 50-day Christian observance of Easter. The term comes from the Greek word for *fiftieth.* Pentecost originally celebrated both the Ascension of Jesus Christ and the descent of the Holy Spirit. In the 300's, the Ascension of Jesus came to be a separate observance. However, Pentecost remained a celebration of the gift of the Holy Spirit to the church, in fulfillment of Jesus's promise "And I will pray the Father, and he shall give you another comforter, that he may abide with you for ever" (John 14:16). During early church history, the term *Pentecost* also referred to the period of 50 days following Easter. This period was the time of the celebration of the Resurrection of Jesus.

In the 1900's, this emphasis was recovered in a number of churches, including the Roman Catholic Church, the Eastern Orthodox Churches, most Lutheran churches, and the churches of the Anglican Communion. In these churches, the season of Easter is observed throughout the seven weeks until Pentecost.

In ancient Israel, Pentecost was the celebration of the wheat harvest held 50 days after the festival of Passover. Since Biblical times, the celebration also commemorates the day the Ten Commandments were revealed to Moses on Mount Sinai. In Judaism, this event is observed in the holiday of Shavuot, which falls in May or June. David G. Truemper

Pentecostal churches, *PEHN tuh KAWS tuhl,* are a group of Protestant churches that trace their origins to a religious revival that began in Topeka, Kansas, in 1901. The movement spread rapidly in the United States. Similar revivals took place in Europe, Asia, and Latin America. Today, some of the world's largest and fastest-growing Protestant denominations are Pentecostal.

Beliefs and practices. Pentecostals claim that all individual Christians should experience "baptism in the Holy Spirit." Proof of "Spirit baptism" generally comes when the person receives the gift of *speaking in tongues*—that is, speaking in an unknown language. Pentecostals take their name from the New Testament reference to the disciples speaking in tongues on the day of Pentecost (Acts 2). Pentecostals also believe that they can receive other gifts of the Holy Spirit. These gifts include the power of physical healing and the abilities to prophesy and to interpret what is said when someone speaks in an unknown tongue. Such gifts are described in I Corinthians 12 and 14.

Pentecostals believe that history will end with the Second Coming of Jesus Christ. They believe their movement fulfills Biblical prophecies of a religious revival before the end of the world. They view *evangelism* (the spreading of their religious message) as a solemn obligation to prepare the world for Jesus's return.

Pentecostal worship services tend to be highly emotional and filled with a sense of the wonder and miracle of the Holy Spirit's presence. The celebration and use of spiritual gifts, as well as prayers for the healing of the sick, are typical practices in many congregations.

Pentecostal churches differ from one another in size and in their interpretations of faith and practice. For example, some Pentecostal denominations are controlled by individual congregations. Other Pentecostal denominations are led by bishops.

Major Pentecostal churches. In the United States, there are about 30 sizable Pentecostal denominations. Many other small, regional churches identify with the Pentecostal movement but do not call themselves Pentecostal churches. In addition, a related movement of *charismatic renewal* began during the 1960's. It involved many Protestants and Roman Catholics who claimed to have experienced Spirit baptism.

The earliest Pentecostal churches grew out of the *Holiness movement* of the late 1800's. Members of Holiness churches acknowledged two acts of grace: (1) conversion, or being "born again"; and (2) sanctification or a "second blessing," meaning a cleansing from sin.

Charles Fox Parham, an independent Holiness preacher, is believed to have originated the Pentecostal revival. In 1901, people began speaking in tongues at his Bethel Bible College in Topeka. Parham claimed that such speech indicated "true baptism in the Spirit." Parham added Spirit baptism to the two acts of grace accepted by Holiness churches. William Joseph Seymour, a black

Holiness preacher, brought the movement to the Azusa Street Apostolic Faith Mission in Los Angeles in 1906.

The first Pentecostal church was the Church of God (Cleveland, Tenn.). This former Holiness church accepted Pentecostal teaching about Spirit baptism in 1907. Other Pentecostal churches with Holiness roots include the Church of God in Christ and the International Pentecostal Holiness Church. See **Church of God in Christ, The.**

Other Pentecostal churches reject the idea of a "second blessing." They teach only conversion and Spirit baptism. One such church, the Assemblies of God, is the largest Pentecostal church. See **Assemblies of God.**

A group of Pentecostal churches known as *Oneness churches* formed out of the Assemblies of God after 1916. These churches reject the traditional Trinity of the Father, the Son, and the Holy Spirit. Instead, they hold that the Bible calls for baptism only "in the name of Jesus." Such churches include the United Pentecostal Church International and the Pentecostal Assemblies of the World, Inc. Penumbra, *pih NUHM bruh,* means *partial shadow.* Suppose an object such as the earth blocks the light given off by a larger source such as the sun. Behind the earth, there is a dark shadow where none of the sun's rays pass. Outside this dark region is another, less dark region, where some of the light passes. This partially dark region is called the *penumbra.* The inner dark region is called the *umbra.* The moon is almost totally dark when it passes through the umbra of the earth's shadow. This occurrence is called a *total eclipse* of the moon.

Diagram of the penumbra. The sun, the source of light, is labeled (a), while (b) is a sphere on which the light falls. The heavily shaded cone behind (b) shows the umbra, where there is almost total darkness. The lightly shaded area shows the penumbra, which is in partial shadow.

You can see an umbra and a penumbra in the shadow of your hand. Hold your hand a few feet from a lamp in a room with no other light. Place a piece of white paper on the other side of your hand. Your hand casts a shadow on the paper. In the center of the shadow of each finger is the dark umbra. Around each umbra is a brighter penumbra. Jearl Walker

Peonage, *PEE uh nihj,* is a system of forced labor in which the *peon* (laborer) is forced to work in payment of a debt. The word *peon* comes from the Spanish *peón,* meaning *day laborer.*

Peonage was common in most of the Spanish colonies of the Americas until the early 1900's, when nearly every civilized country of the world passed laws abolishing the practice. In Mexico, many Indians were forced to work out petty debts. The system was abolished in Mexico in 1917. But the term *peon* is still used to mean the impoverished Indian laborers of Latin America. These agricultural workers live on their employer's land and may receive a small payment for their work.

Peonage existed in the United States, particularly in the present states of New Mexico and Arizona, a short time after slavery was abolished. Blacks were arrested on false charges and fined. If they were not able to pay the fine, they were given to the highest bidder to work without wages for a period of time. At the end of this period, they could be arrested again and forced into service. In 1911, the Supreme Court declared all forms of peonage unconstitutional. Warren Van Tine

Peony, *PEE uh nee,* is the common name of a group of plants with large, handsome flowers. In early spring, peonies have shrubby or herblike stems. The clusters of leafy shoots, red and shiny green in appearance, make a striking effect a few weeks before the flowers appear in late spring or early summer.

Many of the cultivated varieties of peonies common in America are the offspring of two species of the Eastern Hemisphere, the *common peony* of southern Europe and the *Chinese peony.* The large flowers of the common peony are white, red, or crimson and are lovely to look at, although they do not have much fragrance. Many of the Chinese peonies, a large group of hybrids, bear double, sweet-scented blossoms. The peonies with woody stems are called *tree* or *moutan peonies.* This kind of peony is a native of western China. It has showy flowers that blossom in white and rose-colored hues and grow on a stalk from 3 to 4 feet (91 to 120 centimeters) high. Tree peonies grow slowly. In regions of late spring frosts, the buds are often injured. Once established, they bloom season after season. Bush peonies are planted by dividing the shoots.

Scientific classification. Peonies were long placed in the crowfoot family, Ranunculaceae. Today, botanists consider peonies to make up the peony family, Paeoniaceae. The common peony is *Paeonia officinalis;* the Chinese is *P. lactiflora.* Most tree peonies in America are *P. suffruticosa.* Roy E. Gereau

People for the Ethical Treatment of Animals (PETA) is one of the largest animal rights organizations in the world. It promotes the belief that animals deserve moral consideration and should not have to suffer to fulfill human desires. PETA objects to all mistreatment of animals. However, the organization concentrates its efforts on ending the use of animals in research laboratories, in the fur industry, in sports and entertainment, and on *factory farms.* On factory farms, large numbers of food animals are usually raised indoors in pens.

PETA works to achieve its goals through consumer boycotts, educational efforts, lawsuits, protests, and undercover investigations. PETA is well known—and sometimes criticized—for its ambitious media campaigns and sometimes confrontational public demonstrations.

Animal rights activists Alex Pacheco and Ingrid Newkirk founded PETA in 1980. The organization's headquarters are in Norfolk, Virginia. PETA also has offices in Germany, India, and the United Kingdom. Helena Silverstein

Peoria, *pee AWR ee uh* (pop. 112,936; met. area pop. 347,387), is a major industrial center and one of the largest cities in Illinois. It lies in the central part of the state on the Illinois River, about 150 miles (241 kilometers) southwest of Chicago (see **Illinois** [political map]).

Caterpillar Inc., the world's largest maker of earthmoving equipment, has its headquarters in Peoria. The firm is the area's largest employer. Peoria is also the home of the U.S. Department of Agriculture's National Center for Agricultural Utilization Research.

Peoria's Lakeview Center features a museum, planetarium, theater, library, and indoor ice-skating arena. A downtown civic center includes an auditorium, convention hall, and sports arena. RiverFront Peoria, a development along the Illinois River, has parks, sculptures, restaurants, and sports facilities. Deer, elk, and buffalo roam Wildlife Prairie Park, which covers 1,600 acres (647 hectares) west of the city. The Peoria area is the home of Bradley University, Illinois Central College, and a branch of the University of Illinois medical school.

The famous question "Will it play in Peoria?" originated in vaudeville days (see **Vaudeville**). The entertainment industry tested new acts and shows in the city. Peoria later became a test market for consumer products.

The city was named for the Peoria Indians, who originally inhabited the area. The first Europeans to reach the Peoria area were Louis Jolliet, a French-Canadian explorer, and Father Jacques Marquette, a French missionary. They arrived by canoe in 1673. A settlement called Fort Crèvecoeur was established there in 1680. It was soon abandoned but was followed by several other settlements. The town of Peoria was incorporated in 1835.

Peoria has a council-manager form of government. It is the county seat of Peoria County. Jack Brimeyer

Pepin the Short, *PEHP ihn* (714?-768), also called Pepin III, was the first king of the Frankish Carolingian dynasty. The Franks were Germanic peoples who gradually gained control of much of present-day France and Germany and other parts of Western Europe during the early Middle Ages.

In 742, Pepin and his brother Carloman jointly inherited from their father, Charles Martel, the title of Mayor of the Palace. Since the late 600's, mayors had held greater power than the Merovingian kings, who ruled in name only. As mayors, Pepin and Carloman extended Frankish rule to parts of Saxony and Bavaria. After Carloman became a monk in 747, Pepin ruled alone. In 751, with Pope Zachary's help, Pepin deposed the last Merovingian king, Childeric III, and became king of the Franks.

As king, Pepin aided the pope against the Lombards, a Germanic people who had conquered much of Italy. Pepin seized some of the Lombard lands in Italy and gave them to Pope Stephen II in 756. This so-called Donation of Pepin is often seen as forming the core of the Papal States, a territory controlled by the pope until the 1800's. Pepin also added Aquitaine to his kingdom. His son Charlemagne became one of the most powerful rulers in European history. Bernard S. Bachrach

Pepper is a spice that comes from the fruit of several kinds of plants. Black pepper and white pepper are obtained from the fruit of a trailing or climbing vine native to Asia. It was partly the demand for black pepper and other spices that led Christopher Columbus to seek a sea route to Asia, a voyage on which he instead became the first European to visit the New World. Today, most black pepper and white pepper come from Malaysia, India, Indonesia, and other countries with hot climates.

The pepper plant bears a small green berry, which turns red as it ripens. The berries are gathered when they begin to change color. They are cleaned, then dried in the sun or before a fire. In drying, the berries turn black. When they are ground and sifted, they form the black pepper known in most households.

Pepper is a shrubby plant grown for its fruit, which are also called peppers. The fruit develop from the plant's flowers. The pepper plant probably originated in South America. Early American Indians used pepper as a seasoning. In the late 1400's and the 1500's, European explorers brought pepper from America to Europe and Asia. Today, pepper is grown throughout much of the world. In tropical regions, the pepper plant is a *perennial,* which means it lives for at least two growing seasons. In temperate areas, the plant is an *annual* and lives only one growing season.

Pepper fruit consists of a thick, fleshy wall that surrounds a mass of seeds. The wall is eaten fresh as a vegetable. Fresh peppers can also be dehydrated, pickled, and canned for eating. Pepper fruit is ground up to make the spice known as red pepper. Other seasonings that are made from peppers include curry powders and paprika. The spices black pepper and white pepper are made from another kind of plant (see **Pepper** [the spice]).

Many varieties of peppers are grown commercially. The cup-shaped *bell pepper* has three or four *lobes* (rounded sections) and is usually eaten when immature and green. If allowed to mature on the plant, it turns red, yellow, or purple. Other widely cultivated peppers include the long *banana pepper,* the flattened *pimento pepper,* the slender *chili pepper,* and the round *cherry pepper.* Peppers have either a sweet taste or a sharp taste, depending on the amount of a compound called *capsaicin* in the fruit.

John Colwell from Grant Heilman

The green pepper adds color and flavor to food.

Growers raise peppers from seeds. They generally plant the seeds in a greenhouse or in *cold frames* (glas covered boxes). The seedlings are transplanted outdoors after about 8 weeks. Growers use a mechanical transplanter to place the seedlings in the soil about $1\frac{1}{2}$ feet (46 centimeters) apart and in rows about 3 feet (91 centimeters) apart.

Peppers grow best in warm, moist regions with grow ing seasons of over 125 days. Temperatures under 55 °F (13 °C) can inhibit growth and ripening. Growers occasionally spread plastic mulches or other protective coverings over the soil to warm the plants' environment. This extends the growing season.

Pepper plants flower about three to four weeks after transplanting. The plants commonly grow to a height o $3\frac{1}{4}$ feet (1 meter) or more. Growers sometimes support pepper plants with stakes and string to keep them from spreading along the ground.

Diseases caused by bacteria, fungi, and viruses can a tack pepper plants. Insects also feed on the plant's ster leaves, and fruit. Growers control these problems by planting disease-resistant varieties of peppers and by carefully using appropriate pesticides. Hugh C. Price

Scientific classification. Peppers belong to the nightshade family, Solanaceae. Most peppers are varieties of the species *Capsicum annuum.*

Peppermint is a perennial herb of the mint family. Farmers grow it for the fragrant oil produced in its leaves. Peppermint oil is a popular flavoring for candy, and it adds a pleasant taste to many medicines, mouthwashes, and toothpastes. Some medicines for toothaches and colic contain peppermint. Menthol, used in medicines for colds and coughs, is made from peppermint oil. It causes a sensation of coolness in the mouth.

The peppermint plant grows 1 to 3 feet (30 to 91 centimeters) high and bears smooth, sharply pointed, oval leaves and small, purplish flowers. The plant grows be in moist soil containing a large amount of decayed plant matter. Peppermint was developed by crossbreeding the water mint and spearmint plants.

Peppermint originated in Europe, and English colonists brought it to North America. Today, most of the peppermint produced in the United States comes from Oregon and Washington. Idaho, Indiana, and Wisconsin also grow it. Peppermint also grows in the United Kingdom and other European

'epys, *peeps, pehps,* or *PEHP ihs,* **Samuel** (1633- 703), was an English writer and government official. His ımous *Diary* provides an intimate self-portrait and a ivid picture of an exciting period in English history. epys also became known for his role in the develop- ıent of the British Navy.

His diary covers the period from 1660 to 1669. It eals with an early part of Pepys's life, when he was erk of the navy. He wrote the *Diary* in a code combina- on of shorthand, foreign words and phrases, and con- actions of his own invention.

Pepys meticulously recorded events of his daily life. He wrote frankly about his affairs with women and his desire to become wealthy. He described his enthusiasm for music and the theater, and his interest in collecting books and paintings. Pepys told of his public career and his pride in his success. The *Diary* documents his curi- osity about everything, from science to the gossip at the court of King Charles II. Pepys did not intend to have the *Diary* read by the public, and he wrote about himself with unusual honesty.

Pepys recorded many of the important events of the 1660's as a witness and participant. The *Diary* colorfully describes the restoration of the king as ruler of England. The work also contains thrilling accounts of the Great Plague, the Great Fire of London, and England's naval war with the Netherlands. In an especially memora- ble entry, Pepys related his court defense of the navy board after the board came under attack by a parlia- mentary committee.

Samuel Pepys

Pepys stopped writing the *Diary* because his vi- sion deteriorated. The work was first translated from 1819 to 1822 and was published in an abridged edition. The unabridged *Diary* was published in nine volumes from 1970 to 1976.

His life. Pepys was born in London and attended Cambridge University. Through the influence of a pow- erful relative, Sir Edward Montagu, he was appointed clerk of the Acts of the Navy in 1660. This post gave Pepys a position on the navy board. His ability, dedica- tion, and industriousness soon made him the most effi- cient administrator in the navy office.

In 1673, Pepys became secretary of the admiralty and thus, in effect, head of the navy. Under Pepys, the navy administration developed into an efficient, professional organization. Pepys introduced numerous reforms on matters ranging from the appointment of naval officers to the maintenance of dockyards. These standards and procedures were important to the foundation of the modern British Civil Service.

Pepys served in Parliament several times, and he was president of the Royal Society in 1684 and 1685 (see **Royal Society**). He lost his post in the admiralty after the fall of King James II in 1688. Pepys then wrote *Mémoires of the Royal Navy, 1679-1688,* which was published in 1690. Gary A. Stringer

Percentage attracts shoppers because it shows how much a buyer can save on a store's regular prices. A sale at "25% off" means that regular prices have been reduce by $\frac{25}{100}$ or .25 or $\frac{1}{4}$ for a certain period of time.

Percentage refers to computing by hundredths. You often see numbers such as 2%, 30%, and 75%. The % symbol means *percent.* You read the numbers "2 percent," "30 percent," and "75 percent." *Percent* means *hundredths:* 2% means 2 hundredths, 30% means 30 hundredths, and 75% means 75 hundredths. Percentages are really *common fractions:* 2% is $\frac{2}{100}$, 30% is $\frac{30}{100}$, and 75% is $\frac{75}{100}$. In addition, percentages are *decimal fractions:* 2% is .02, 30% is .30, and 75% is .75. Suppose you want to find 25% of 60. You must find $\frac{25}{100}$, or .25, of 60. The term *percent* is from two Latin words meaning *by the hundreds.*

We use percentage frequently in everyday life. Bankers use percentage to compute interest on savings and loans. Our taxes are percentages of income, prices, and other amounts. Scientists often show the results of their observations and experiments with percentages. In baseball, team standings and batting averages are based on percentages. On clothing labels, percentages often represent the amounts of different fibers that are in the garment.

For hundreds of years, the business world has used the term *percent,* and this custom has persisted to the present time. The custom may come from Roman taxes, which were often stated as $\frac{1}{20}$, $\frac{1}{25}$, $\frac{1}{100}$, and so on. In the Middle Ages, merchants commonly used hundredths and percentages even before the appearance of the decimal number system (see **Decimal system**).

After the introduction of the decimal system, people no longer needed to use the term *percent.* It is just as easy to work with .25 as it is to work with 25%. However, percentage had become so deeply woven into business, professional, and everyday life that use of the term continued.

How to change percentages to fractions

Percent, in English, means *hundredths.* To change a percentage to a common or decimal fraction, you need only write the percentage as hundredths.

Changing percentages to common fractions. To change a percentage to a common fraction, drop the % symbol and write in a denominator of 100. Here are fou examples:

$25\% = \frac{25}{100} = \frac{1}{4}$ $\quad$ $37.5\% = \frac{37.5}{100} = \frac{3}{8}$

$125\% = \frac{125}{100} = 1\frac{1}{4}$ $\quad$ $265\% = \frac{265}{100} = 2\frac{13}{20}$

Changing percentages to decimal fractions. To change a percentage to a decimal fraction, drop the % symbol and write in a decimal point two places to the left. Here are four examples:

25%=.25 $\quad$ 37.5%=.375

125%=1.25 $\quad$ 265%=2.65

How to change fractions to percentages

Changing common fractions to percentages. To change a common fraction to a percentage, divide the numerator by the denominator to get a decimal fractior Then move the decimal point two places to the right and attach the % symbol. Here are four examples:

$\frac{3}{5}$ =3÷5=.60 (60 hundredths)=60%

$\frac{5}{8}$ =5÷8=.625 (62.5 hundredths)=62.5%

$\frac{2}{3}$ =2÷3= .66 $\frac{2}{3}$ (66 $\frac{2}{3}$ hundredths)= 66 $\frac{2}{3}$%

$\frac{7}{4}$ =7÷4=1.75 (175 hundredths)=175%

Changing decimal fractions to percentages. To change a decimal fraction to a percentage, move the decimal point two places to the right and attach the % symbol. Here are four examples:

.07 (7 hundredths)=7%

.63 (63 hundredths)=63%

.625 (62.5 hundredths)=62.5%
1.52 (152 hundredths)=152%

Solving percentage problems

Because percent means hundredths, you should re-
tate any percentage problem in terms of decimal or
ommon fractions. Then you can solve it fairly easily as a
raction problem.

How to find a percentage of a number. Suppose
ou want to find 4% of 50. This means you want to find 4
undredths of 50. First, change 4% to a common or deci-
nal fraction.

$$4\% = \frac{4}{100} \qquad 4\% = .04$$

n order to find 4% of 50, you must multiply 50 by the
action that 4% represents:

$$\frac{4}{100} \times 50 = \frac{200}{100} = 2 \qquad .04 \times 50 = 2$$

o 4% of 50 is 2.

Here are some more examples:
ind 30% of 72.

$$30\% = \frac{30}{100} \qquad 30\% = .30$$

$$\frac{30}{100} \times 72 = \frac{2160}{100} = 21.6 \qquad .30 \times 72 = 21.6$$

30% of 72 is 21.6

ind $66\frac{2}{3}$% of 915.

$$66\tfrac{2}{3}\% = \frac{66\frac{2}{3}}{100} = \frac{200}{300} = \frac{2}{3} \qquad 66\tfrac{2}{3}\% = .66\tfrac{2}{3}$$

$$\frac{2}{3} \times 915 = \frac{1830}{3} = 610 \qquad .66\tfrac{2}{3} \times 915 = 610$$

$66\frac{2}{3}$% of 915 is 610

ind 250% of 32.

$$250\% = \frac{250}{100} = \frac{5}{2} \qquad 250\% = 2.5$$

$$\frac{5}{2} \times 32 = 80 \qquad 2.5 \times 32 = 80$$

250% of 32 is 80

What percentage is one number of another? Look
the statement 20 = 4 × 5. The numbers 4 and 5 are
ctors of 20. When you multiply these factors, you get
e product 20. Suppose the factor 5 is missing: 20 = 4
?. You can find the missing factor by dividing 20 by 4:
) ÷ 4 = 5. Suppose the factor 4 is missing from the
atement: 20 = ? × 5. You can find it the same way: 20 ÷
= 4.

Now suppose one of the factors is a fraction. Look
refully at the problem 30 = ? × $\frac{1}{4}$. You can find the
issing factor by dividing 30 by $\frac{1}{4}$:

$$30 \div \frac{1}{4} = 30 \times \frac{4}{1} = 120$$

) 30 = 120 × $\frac{1}{4}$. Percentages are hundredths, so you
n use this process to find what percentage one num-
r is of another.

Suppose you want to find what percentage of 30 the
mber 15 is. First, write the problem in the form 15= ?
30. You can find the missing factor by dividing 15 by
:

$$15 \div 30 = .5 \qquad .5 = 50\%$$

15 is 50% of 30.

Here are two more examples:
17 is what percentage of 340?

$$17 = ? \times 340$$
$$17 \div 340 = .05 \qquad .05 = 5\%$$

17 is 5% of 340

420 is what percentage of 70?

$$420 = ? + 70$$
$$420 \div 70 = 6 \qquad 6 = 600\%$$

420 is 600% of 70

These problems can also be solved by comparing ra-
tios. For example, in determining what percentage of 30
the number 15 is, you are attempting to find a number
that compares to 100 in the same way that 15 compares
to 30. That is, you are looking for the number that, with
100, expresses the same ratio as the ratio of 15 to 30:

$$\frac{15}{30} = \frac{?}{100} \qquad 15 \times 100 = 30 \times ? \qquad \frac{1500}{30} = 50$$

So 15 is 50% of 30.

Finding a number when a percentage is known.
Suppose you know that 6 is 25% of some number. What
is the number? You can use the process of finding a
missing factor to solve this problem. First, write the
problem in the form 6 = 25% × ?. Now 25% is .25, so the
problem becomes 6 = .25 × ?. You can find the missing
factor by dividing 6 by .25:

$$6 \div .25 = 24$$

So 6 is 25% of 24.

Here are some more examples:
17 is 40% of what number?

$$17 = .40 \times ? \qquad 17 \div .40 = 42.5$$

17 is 40% of 42.5

46 is 115% of what number?

$$46 = 1.15 \times ? \qquad 46 \div 1.15 = 40$$

46 is 115% of 40

Applications of percentage

Commissions. Many companies pay their salespeo-
ple by giving them a *commission* (a certain amount of
money for each article they sell). The commission is usu-
ally a certain percentage of the price of the article that is
sold.

Suppose a salesman receives a 15 percent commis-
sion on everything he sells. How much money does the
salesman earn if he sells a refrigerator for $749? That is,
what is 15 percent of $749? First, remember that 15 per-
cent means 15 hundredths. You must find .15, or $\frac{15}{100}$, of
749.

$$15\% = \frac{15}{100} \qquad 15\% = .15$$

$$\frac{15}{100} \times \$749 = \$112.35 \qquad .15 \times \$749 = \$112.35$$

So the salesman earns $112.35 on the sale.

Comparisons. Percentage gives us a method of com-
paring quantities. It helps to make a comparison where
the relationship is not easy to see at once. For example,
percentage helps people to compare volumes of sales
on the stock market. Companies often use percentage to
compare their business gains and losses. Engineers use
percentage to compare production rates with their

goals. Here is a more familiar example taken from the records of three baseball teams:

Boston Red Sox won 12 games and lost 8 games.
Toronto Blue Jays won 13 games and lost 9 games.
New York Yankees won 11 games and lost 6 games.

What is the correct standing of the teams?

To determine standing, you can compare the number of games won by each team to the number of games that team has played. First, you can see that the Boston Red Sox played 20 games and won 12 of them. What percentage of 20 is 12? Remember the process of finding a missing factor.

$$12 = ? \times 20$$
$$12 \div 20 = .60 \qquad .60 = 60\%$$

So the Boston team won 60 percent of its games.

The Toronto Blue Jays played 22 games and won 13 of them. What percentage of 22 is 13?

$$13 = ? \times 22$$
$$13 \div 22 = .591 \qquad .591 = 59.1\%$$

The Toronto team won 59.1 percent of its games.

The New York Yankees played 17 games and won 11 of them. What percentage of 17 is 11?

$$11 = ? \times 17$$
$$11 \div 17 = .647 \qquad .647 = 64.7\%$$

The New York team won 64.7 percent of its games.

Now you can arrange the teams on the basis of the percentage of games won:

Team	Percentage
New York Yankees	64.7
Boston Red Sox	60
Toronto Blue Jays	59.1

You can use percentage to compare other quantities.

Interest. When people borrow money from a bank, the bank charges them *interest* on the loan. Paying interest is like paying rent for the use of the money. Bankers usually compute interest by percentage.

Suppose a businesswoman borrows $6,000 from the bank. The bank charges her 9 percent interest a year. How much interest does she have to pay every month? First, what is 9 percent of $6,000?

$$9\% = .09$$
$$.09 \times \$6{,}000 = \$540 \qquad 9\% \text{ of } \$6{,}000 = \$540$$

So the businesswoman must pay the bank $540 on her loan for one year. To find how much she must pay for one month, divide $540 by 12:

$$\$540 \div 12 = \$45$$

So the businesswoman must pay the bank $45 every month as interest on her loan. See **Interest**.

Profits. Businesses usually charge a price for an article that includes the article's cost and the company's own profit. This price is the *selling price*. Businesses usually compute their profits as percentages.

Suppose a dealer bought a bicycle from a manufacturer for $360. The dealer wants to make a profit of 25 percent of the price for which the bicycle is sold. How much must the dealer charge for the bicycle and what will the profit be? To make a profit of 25 percent, the cost of the bicycle from the manufacturer must be 75 percent of the price the dealer charges. So the problem is to find the number of which $360 is 75 percent. Remember the process of finding a missing factor.

$$75\% = .75$$
$$\$360 = ? \times .75$$
$$\$360 \div .75 = \$480 \qquad \$480 - \$360 = \$120$$

So the dealer must charge $480 for the bicycle. The profit will be $120. As a check, you can see that the profit, $120, is 25 percent (or one-fourth) of the selling price of $480.

Taxes. A large number of prices include taxes. For example, the price of a bracelet could include both federal and state tax charges. These taxes are usually computed as percentages of an article's price before the tax was added.

Suppose a college sells tickets for a football game. Each ticket costs $30. The $30 price includes a 10 percent federal tax on the college's income from the ticket. What is the income from each ticket? If the $30 price includes both income and the 10 percent tax, then the $30 must represent 110 percent of the income. So the problem is to find the number of which $30 is 110 percent.

$$110\% = 1.10$$
$$\$30 = ? \times 1.10$$
$$\$30 \div 1.10 = \$27.27 \textit{ (to the nearest cent)}$$

So the income that the college earns from each ticket sold is $27.27. Nadine L. Verderber

Perception is the process by which we observe and find meaning in the objects, events, and people around us. Our knowledge of the world comes through our sense organs, which react to various kinds of energy and physical signals. Our eyes respond to certain wavelengths of light. Our ears sense certain kinds of vibrations in the air. Our noses and tongues are sensitive to certain chemical signals. Sense organs in our skin respond to pressure, temperature, and pain. Sense organs in our joints, tendons, and muscles respond to body movement and position.

Sense organs change the various physical signals into nervous impulses, and these impulses then travel to the brain. Through the psychological process of perception, the patterns of signals come to exist in our minds as objects, events, people, and other aspects of the world.

Perception involves an active process of "working on" sensory data to produce objects and events. This "work" involves many physical and psychological factors. For example, there is no music or noise in the vibrations that stimulate the ear. The brain organizes and interprets nervous impulses from the ears as sound. Together, the sense organs and the brain transform physical energy from sound waves and other environmental stimuli into information about the events around us.

Factors affecting perception

Both physical and psychological factors influence perception. One of the most important physical factors is the structure of the human nervous system. Important

ɪsychological factors include our emotions, needs, ex-
ɪectations, and learning.

The nervous system. Each sensory system, such as
ision, hearing, or touch, has its own specialized detec-
ors. These detectors are called *receptors,* and they
unction in various ways to change energy into nervous
npulses. For example, the human eye has two major
inds of receptors in the *retina* (the light-sensitive part of
he eye). These receptors are called *rods* and *cones.*
ods and cones each contain particular chemicals that
espond to light in different ways. As a result, rods de-
ect shape, movement, and shades of gray, but do not
espond to other colors. Cones, however, detect the full
ange of color by responding to different frequencies of
ght. These differences in structure and function help
etermine the perceptual effects related to rods and
ones. Rods enable us to see in dim light, and cones en-
ble us to see colors and sharp detail in bright light.

The brain. Certain physical and functional features of
ne brain also influence perception. The part of the brain
nat interprets visual signals has different kinds of cells
nat respond only under certain conditions. Some of
nese cells respond when a light is lit, but they stop re-
ponding if the light stays on. Others respond only
/hen a light turns off. These cells also are arranged in
pecial ways that are related to how we perceive. For ex-
mple, some cells occur in columns or in clusters that
re related to how we perceive edges and forms.

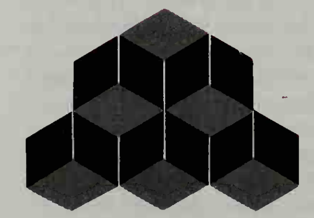
Learning, emotion, and motivation. Much evi-
ence supports the conclusion that learning, emotion,
nd motivation are important influences on perception.
art of this evidence comes from experiments that com-
are how people in different cultures perceive things.
he perception of form, color, pain, touch, and other ex-
eriences may differ from culture to culture, depending
n habits, customs, and training of children.

Look at the illustration of perceptual effects in this ar-
cle for a simple example of how learning can affect
erception. Read the phrases inside the two triangles at
ie top of the picture. Did you fail to see the duplicate
ords? Most people do, and many experienced readers
ɔntinue to miss the duplicate word even with repeated
eadings. In learning to read, we learn not to perceive
ich letter and word separately. As our skill improves,
e become increasingly able to scan the overall pattern
ıd "fill in" the rest. This tendency to notice overall
eaning increases the chance that an experienced read-
will overlook the duplicated word in each phrase. A
ader who still reads word by word is more likely than
ı advanced reader to see the repeated word.

Visual effects called *illusions* can also demonstrate
e influence of learning and past experience. An illu-
ɔn is not a false perception, as many people believe,
ıt one that is inconsistent with another perception.
ɪok at the two triangular patches of gray containing
ack and white detail in the illustration of perceptual ef-
cts. If you see the patches as being different shades of
ay, then you are experiencing an illusion. The patches
e the same shade of gray.

Emotions and motivation can have important effects
ı perception. At times, severe emotional disturbance
n prevent perception completely. For example, some
ople who are robbed are unable to remember any-
ng about the appearance of the robber. Motivation
can also affect the way we perceive. For example, food
may seem unusually large or colorful to hungry people.

Understanding perception



Types of perception. Perception has three levels of
complexity: (1) *detection,* (2) *recognition,* and (3) *discrimi-
nation.* Detection refers to whether people can sense
that they are being stimulated by some form of energy.
For example, a light may be so dim that people can
barely see it. Recognition means being able to identify
as well as detect a particular pattern of stimulation. Dis-
crimination means being able to perceive patterns of
stimulation as different. For example, a person may

hear slight differences between two similar musical tones.

The field of study that deals with the levels of perception is called *psychophysics.* Psychologists investigate relationships between the physical properties of stimulus patterns and the perceived effects of the stimuli. For example, they may study the relationship between sound frequency and the perceived pitch of the sound.

Principles of perception. There are a number of general principles that help us understand the process of perception. One of the most important of these principles is the idea of *closure.* Closure is the general psychological tendency to perceive things as complete and unified. We tend to "fill in" parts that are missing, or parts that conform to an overall impression.

The principle of *constancy* states that we tend to perceive objects as constant in size, shape, color, and other qualities in spite of changes that occur in stimulation. For example, an orange will be perceived to have its characteristic color under different kinds of light. The opposite of the principle of constancy is also important. Sometimes an object or pattern of stimulation will remain constant, but the perceived effect will vary. For example, look at the gray and black cubes in the illustration of perceptual effects. At one moment you may see three complete cubes, but at another moment you may see five.

Another important principle relates to *perceptual context.* The perception of an object or event depends in part on the *context* (surrounding conditions). Look at the two rectangles containing the words *World Book* in the illustration. The words are printed with the same ink. Do they look the same? Background intensity and color may affect the color and intensity of elements upon it. To most people, the letters surrounded by black appear brighter and somewhat larger than the letters surrounded by gray. This effect is called *visual induction.* Notice, too, that the effect is opposite to that observed with the two gray triangles with black and white detail. In this case, the gray with black detail appears darker rather than brighter. William M. Smith

Perch is the name of a family of about 165 species of freshwater fish that live in the Northern Hemisphere. The larger species, such as the *yellow perch, walleye,* and *sauger,* are popular game fish. About 150 of the smaller species in the perch family belong to a group called *darters.* Perch are in the group of bony fish called *teleosts,* to which most common fish belong.

The name *perch* is most commonly given to the yellow perch of North America. This golden-yellow fish is also called the *ringed perch* and *common perch.* It grows from 5 to 12 inches (13 to 30 centimeters) long and weighs up to 4 pounds (1.8 kilograms). Its sides are marked with several dark bars. The yellow perch is an important food fish. It ranges from the Chesapeake Bay region northward into Canada and also throughout the upper Mississippi River basin. A similar species is common in Europe.

The walleye measures 12 to 36 inches (30 to 90 centimeters) long and weighs up to 24 pounds (11 kilograms). The sauger grows to 28 inches (71 centimeters) long and weighs about 9 pounds (4.1 kilograms). Both species inhabit the Great Lakes and lakes, rivers, and streams throughout the Mississippi River basin and into Canada. The walleye is also known as the *pike, pickerel, walleyed pike, pike perch,* and *jack salmon.*

Darters are found only in North America. Males are brightly colored, especially during the breeding season. The *least darter* measures from 1 to 1 $\frac{1}{4}$ inches (2.5 to 3.0 centimeters) long and weighs about $\frac{1}{30}$ ounce (1 gram). It is the smallest fish in the perch family. See **Darter**.

The *bluegill, longear sunfish,* and *pumpkinseed* are sometimes referred to as perch. But they are actually in the sunfish family. Charles H. Hocutt

Scientific classification. Perch are in the freshwater perch family, Percidae. The yellow perch is *Perca flavescens.* The walleye is *Stizostedion vitreum vitreum* and the sauger, *S. canadense.* The least darter is *Etheostoma microperca.*

Peregrine falcon, *PEHR uh grihn,* is a bird of prey that can travel faster than any other animal. It makes *stoops* (steep dives) that may exceed 200 miles (320 kilometers) per hour. Peregrines, sometimes called *duck hawks,* are also among the most widely distributed birds. They live on every continent except Antarctica.

Peregrine falcons grow about 15 to 20 inches (38 to 51 centimeters) long. Females are about a third larger than males. Peregrines vary in color from brownish when young to dark blue or bluish-gray when mature. The bird's underside is lighter in color, and dark markings occur all over the body. A black, helmetlike crown of feathers covers the male peregrine's head and neck.

Peregrines prefer to nest on high cliffs or even ledges of skyscrapers. The females usually lay three or four eggs each year.

Peregrines chiefly eat live birds. They swoop down on their prey from great heights and knock it from the sky. Peregrines may hunt birds as large as geese, but they prefer smaller prey, such as pigeons and ducks.

People have used peregrines as hunting birds for centuries. In the late 1940's and the 1950's, the peregrine population declined dramatically due to harmful pesticides. These pesticides caused thinning of peregrine egg shells, which killed the young before they hatched. By 1960, peregrines had vanished from most of North America. But beginning in the 1970's, pesticide restrictions and other measures led to the birds' gradual recovery. Charles van Riper III and Sandra van Riper

Scientific classification. The peregrine falcon belongs to the falcon family, Falconidae. It is *Falco peregrinus.*

Perelman's targets included advertising, best-selling fiction, the Hollywood motion picture industry, and the behavior of American tourists when they visited other countries.

Sidney Joseph Perelman was born in the Brooklyn section of New York City. He grew up in Providence, Rhode Island, the setting of several of his works. Follo

ıg the success of his first book, *Dawn Ginsbergh's Re-enge* (1929), he went to Hollywood to write screen-lays. He helped write the scripts for two of the Marx rothers' best-known comedies, *Monkey Business* (1931) nd *Horse Feathers* (1932). 'erennial, *puh REHN ee uhl,* is a plant that lives for ıore than two years or growing seasons. Some peren-ials, such as trees, can live for hundreds of years. erennials differ from *annuals,* which complete their life ycles in a single year, and from *biennials,* which live vo years or growing seasons. See **Annual; Biennial.**

Perennials are either *woody* or *herbaceous* (non-'oody). Woody perennials, which include trees and ırubs, develop stems that increase in diameter each rowing season. They do this by adding new tissues, ıostly wood, to those of previous seasons. The above-round parts of herbaceous perennials die each season, ut the underground parts produce new shoots the next ear. Herbaceous perennials include asparagus, rhu-arb, and many spring wildflowers. Joseph E. Armstrong

He became ime minister again in 1995 following the assassination Prime Minister Yitzhak Rabin. In 1996, Peres lost in na-ɔnal elections, and Benjamin Netanyahu of the Likud oc replaced him as prime minister.

In the early and middle 1990's, both as foreign minis-r under Rabin and as prime minister himself, Peres ayed a major role in a move for peace between Israel ıd the Palestine Liberation Organization (PLO). Peres, ıbin, and PLO leader Yasir Arafat shared the 1994 No-el Peace Prize for their peace efforts.

Peres served as prime minister in the unity govern-ent created by the Labor Party and Likud in September 984. The parties formed the government after no party on a majority in parliamentary elections. The unity gov-nment lasted for 50 months. Under the agreement be-een Labor and Likud, Peres—head of the Labor Party—rved as prime minister for 25 months. Yitzhak Shamir, ad of Likud, was vice prime minister and foreign min-er. Under the agreement, Peres and Shamir reversed les after 25 months—in October 1986. As prime minis-r, Peres pledged to withdraw Israeli troops that had in-ded Lebanon in 1982. In 1985, the Israeli forces with-ew from all of Lebanon cept a Security Zone ɔng the Israeli border.

In 1988, Labor and Likud rmed a new coalition vernment with Shamir prime minister. Peres re-ıined as vice prime min-er and also became fi-nce minister. In 1990, the alition collapsed, and res resigned from his sts as vice prime minis- and finance minister. ud and small parties formed a new coalition government in June with Shamir as prime minister. Peres had become head of the Labor Party in 1977. In 1992, he lost that post in a party election.

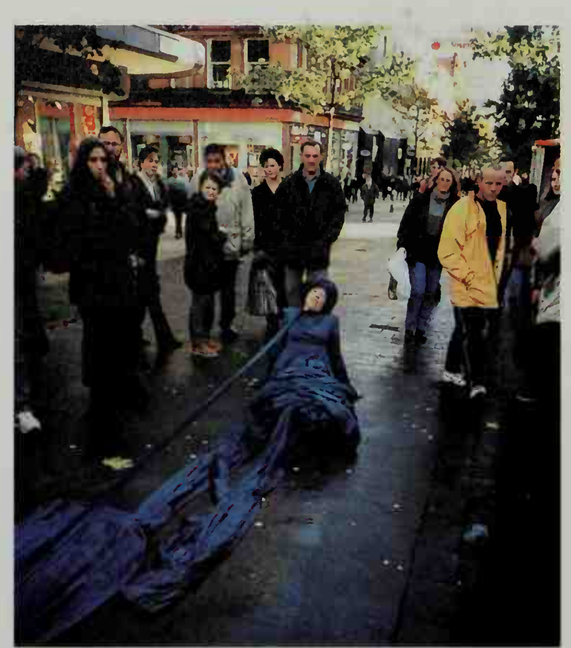
Peres was born on Aug. 16, 1923, in Vishnevo, a small town near Minsk, that was then part of Poland and is now part of Belarus. His family name was Persky. He changed the name to Peres in the 1940's. Peres moved with his family to Palestine in 1934. He later became active in the movement that resulted in the creation of the nation of Israel in Palestine in 1948. In 1950, Peres was sent to the United States as leader of a defense ministry delegation. He returned to Israel in 1952. Peres was first elected to the Israeli *Knesset* (parliament) in 1959. He helped form the Labor Party in 1968. He was minister of defense from 1974 to 1977. He served as foreign minister in 1987 and 1988 and from 1992 until 1995. In 2001, he again became foreign minister. Malcolm C. Peck

He was the UN's fifth secretary-general and its first from Latin America. Pérez de Cuéllar worked to improve the UN's administrative efficiency. He also took part in negotiations on conflicts in Afghanistan, Central America, Cyprus, the Falkland Islands, and the Persian Gulf. In 1988, he helped negotiate a truce between Iran and Iraq. In 1991, he led talks that resulted in a treaty ending a civil war in El Salvador.



Pérez de Cuéllar was born in Lima, Peru, on Jan. 19, 1920. He received a law degree at the Catholic University in Lima in 1943 and entered Peru's foreign service in 1944. He was Peru's ambassador to Switzerland, Venezuela, and the Soviet Union and, in 1971, became Peru's delegate to the UN. Pérez de Cuéllar served as prime minister of Peru for several months in 2000 and 2001. In 2001, he became Peru's ambassador to France and representative to UNESCO. Michael J. Berlin

Performance art is a live performance that combines elements from many branches of art. Performance artists use literature, the visual arts, popular culture, music, dance, and theater, as well as video, slides, and computer-generated images. A performance can consist of one person or several and may take place anywhere and last for any length of time. It often uses the performer's body as the primary art medium. It may be autobiographical or make a political statement, especially of a radical nature. Performances often merge art with daily activities.

Performance art grew out of *avant-garde* (experimental) art movements of the early 1900's, particularly Dada and Futurism and the work of the French artist Marcel Duchamp. From the 1940's through the 1960's, these international movements were linked with such American movements as Abstract Expressionism, Minimalism, Pop Art, and Conceptual Art. Artists who pioneered the performance movement in America include composer John Cage, painter and sculptor Allan Kaprow, and sculptor Claes Oldenburg. During the 1960's, all three artists created a form of performance art called *happenings.* Happenings combined sound and visual material in random ways, often with the audience participating.

During the late 1900's, performance art became more concerned with social and political issues, such as feminism or AIDS awareness. Leading performance artists

Perfume is a substance that gives off a pleasing fragrance. Perfumes are made of natural or *synthetic* (artificially created) materials, or a combination of both. People who make perfumes are called *perfumers.*

People use perfumes in many ways to create a pleasant odor. They apply paste and liquid perfumes to their bodies and clothing. They use lipsticks, face and body lotions and powders, and other cosmetics that contain perfume. By far the largest amount of perfume is used in soaps, especially bar soaps. Industrial *odorants* (low-priced, scented substances) are added to some products to hide unpleasant odors and make the products attractive to buyers. Paper, plastic, and rubber products are often treated with odorants. Since ancient times, plants and plant products with pleasing odors have been burned as incense during religious services.

All liquids used for body scenting, including colognes and toilet waters, are sometimes considered perfumes. But *true perfumes*—called *extracts* or *essences*—have a greater amount of perfume oils and are more expensive than colognes and toilet waters. Most perfumes consist of 10 to 20 percent perfume oils dissolved in alcohol. Colognes contain 3 to 5 percent perfume oils dissolved in 80 to 90 percent alcohol, with water making up the balance. Toilet waters have about 2 percent of perfume oils in 60 to 80 percent alcohol, and the balance is water.

How perfumes are made

The composition of a perfume depends largely on its intended use. Most expensive body perfumes contain rare flower oils from many parts of the world. Perfumes used in soapmaking come from low-cost materials. Industrial odorants also consist mainly of low-cost fragrances. Many perfumes are blends of flower and plant oils, animal substances, synthetics, alcohol, and water.

Plant substances. The substances that give fragrant plants their pleasant odor are called *essential oils.* Essential oils taken from flower petals are used in the most delicate and expensive perfumes. Essential oils also come from bark, buds, leaves, rinds, roots, and wood, or from whole plants. Plant oils used in perfumes include citronella, geranium, jasmine, lavender, patchouli, rose, rosemary, sandalwood, and tuberose.

Much essential oil is *extracted* (obtained) from plants by *steam distillation.* The first step in this process is to pass steam through the plant material. The essential oil turns to gas, which is then passed through tubing and cooled to make it liquid again. Essential oil is obtained from some flowers by boiling the petals in water.

Solvent extraction is an important way of obtaining essential oils from flowers. The petals are dissolved in a *solvent* (liquid that can dissolve other substances). The solvent is distilled from the solution, leaving a waxy material that contains the oil. This material is placed in ethyl alcohol. The oil dissolves in the alcohol and rises with it to the top of the wax. Heat is applied, and the alcohol evaporates, leaving concentrated perfume oil.

Enfleurage is another method of extracting flower oil. Glass plates are covered with fat, and flower petals are spread over the fat. The fat absorbs the oil from the petals, forming a greasy *pomade.* The pomade is treated with alcohol to dissolve out the oil.

Animal substances slow the evaporation of perfume oils and make the fragrances long-lasting. For this reason, they are often called *fixatives.* Perfume ingredients from animals include castor, from the beaver; civet musk, from the civet; musk, from the male musk deer; and ambergris, from the sperm whale.

Synthetic substances account for the largest
mount of materials used in the perfume industry. The
aw materials for these substances may be obtained
om natural sources, petrochemicals, or coal tar. Some
ynthetic materials have the same chemical makeup as
aturally occurring materials. Others are different from
ny material found in nature. Many synthetic odors have
een developed throughout the world to meet the in-
reasing demand for perfumes and to add to the cre-
tive development of the perfume industry.

History

Ancient peoples burned fragrant resins, gums, and
oods as incense at their religious ceremonies. The
ord *perfume* comes from the Latin words *per,* mean-
ıg *through,* and *fumus,* meaning *smoke.*

Perfumes have been found in the tombs of Egyptian
haraohs (rulers) who lived more than 3,000 years ago.
he Egyptians soaked fragrant woods and resins in
ater and oil, and then rubbed their bodies with the liq-
d. They also *embalmed* (preserved) their dead with
ıese liquids. The ancient Greeks and Romans learned
bout perfumes from the Egyptians.

For hundreds of years, perfume making was chiefly
ı Oriental art. In the early 1200's, the crusaders brought
erfume from Palestine to England and France. By the
500's, perfumes had become popular throughout Eu-
ope. Synthetic chemicals have been used extensively in
erfumes since the late 1800's. Today, the perfume in-
ustry is a billion-dollar-a-year business in the United
ates. Patricia Ann Mullen

ericles, *PEHR uh KLEEZ* (490?-429 B.C.), was a Greek
tesman whose name was given to the greatest period
the history of ancient Athens. He was the leader of the
henian government for more than 30 years, and the
e of Pericles came to stand for all that was highest in
art and science of the ancient world.

Pericles was born in Athens, a member of a high-
king noble family. He was educated by the greatest
ilosophers of his day. His mother was a niece of Cleis-
nes, a statesman who had made many democratic re-
ms in the Athenian government (see **Cleisthenes**).
isthenes had given the governing power to the as-
nbly and popular courts. But because officials then
received no pay, the poor could not afford to hold of-
fice. After Cleisthenes' death, the *Areopagus,* a council
of prominent citizens, took back its power over the city.

Pericles was determined to continue the reforms of
his great-uncle and entered politics with the democratic
popular party. He and Ephialtes, the leader of this party,
worked to limit the power of the Areopagus. But Cimon,
leader of the aristocratic party, opposed Pericles. Peri-
cles managed to have his rival *ostracized* (banished) for
favoring the Spartans.

Athenian leader. In about 460 B.C., Ephialtes was
killed. Pericles became leader of the popular party and
the most powerful person in the state. He made many
changes as head of the state. Public officials had never
been paid before, but Pericles introduced salaries, first
for the elected officials called *archons,* and later for all
officers. According to Aristotle's *Constitution of Athens,*
as many as 20,000 people were on the public payroll. In
457 B.C., Pericles made his greatest reform. The com-
mon people were allowed to serve in any state office.

Pericles wanted to make Athens the most powerful
state in Greece. He tried to expand the power of Athens
by foreign conquest. Athenian troops fought in Egypt,
Boeotia, and the Aegean Islands. This angered Sparta,
and the two states broke off friendly relations.

War with Sparta. Pericles' wars were not all success-
ful, and Cimon was allowed to return from exile to lead
the armies. Cimon fought successfully against Persia,
and Athens made a favorable peace with that country in
449 B.C. Three years later, Athens signed a 30 years'
peace treaty with Sparta allowing Athens to keep Ae-
gina, Euboea, and the cities of the Delian League. But
Pericles feared there could be no peace with Sparta, for
the Spartans were jealous of Athenian power.

The Athenians had moved the treasury of the Delian
League from Delos to Athens during the war with Persia.
Pericles persuaded the Athenians to use this money and
the money paid by the subject states to build up the
Athenian navy and to beautify Athens. He employed the
finest architects and sculptors to build and decorate the
temple of Athena Nike, the Propylaea, the Parthenon,
and many other structures. The state enjoyed prosperity,
and literature and philosophy flourished.

The Peloponnesian confederacy, headed by Sparta,
declared war on Athens in 431 B.C. Pericles persuaded
the Athenians to adopt a new and difficult strategy. He
called all the people of the surrounding districts into the
city and allowed the Spartans and their allies to lay
waste to the surrounding districts as they pleased. Peri-
cles continued to build up the navy with the hope that
Athens could defeat the Spartans with sea power. In 430
B.C., a plague broke out in the city, and many people
died. The Athenians began to blame Pericles for all their
troubles, and for a short while removed him from
power. But he was soon restored to office. Pericles died
of the plague during the war. Donald Kagan

Peridot, *PEHR uh daht,* is a transparent gem that is al-
most always some shade of green because of its iron
content. Peridots are a variety of a common rock-
forming mineral called *olivine.* Jewelers cut and polish
the highest-quality peridot stones so that each gem has
many flat surfaces called *facets.* Faceted peridots are

used in all types of fine jewelry. Jewelers cut lesser-quality peridots into a rounded style called *cabochon,* or polish them with abrasives in a process called *tumbling.* These lesser-quality peridots are used in costume jewelry and decorative objects. Peridot is one of the two birthstones for August.

Peridots have been known since Biblical times. The earliest source of peridots was Jazirat Zabarjad (St. John's Island), off the Egyptian coast in the Red Sea. In the United States, Arizona and New Mexico are important commercial sources of peridots. Pansy D. Kraus

Periodontitis, *PEHR ee oh dahn TY tihs,* is a disease of the gums and of the bone that supports the teeth in their sockets. Periodontitis, also called *pyorrhea alveolaris,* is the chief cause of tooth loss after age 35.

The most common form of periodontitis results from the build-up of *plaque* on the teeth and gums. Plaque is a sticky mixture of food particles and bacteria. The bacteria and their waste products irritate the gums and produce *gingivitis,* an inflammation of the gums (see **Teeth** [Periodontal diseases]). If gingivitis is not treated, the gums become swollen and bleed easily, and in time they may recede from the teeth. The bacteria then attack the connective fibers that line the teeth sockets, and pus forms in the narrow pockets between the teeth. The spreading infection destroys the fibers and surrounding bone that hold the teeth in their sockets. As periodontitis progresses, the teeth become loose and may fall out of their sockets.

Periodontitis is curable in its early stages. A dentist should be consulted if the gums are red and tender and bleed easily. Certain drugs may be prescribed in the initial treatment of the disease. Later treatment consists largely of removing plaque, grinding off rough surfaces of the teeth, surgically removing the diseased gums, and reshaping bone. Proper dental care, including daily brushing and flossing, helps prevent the disease.

Peripatetic philosophy, *PEHR uh puh TEHT ihk,* was established by the Greek philosopher Aristotle. Many scholars believe the word *peripatetic* may be traced to a Greek word meaning *a covered walk.* At the Lyceum, a school Aristotle founded in Athens, students were taught beneath a covered walk called a *peripatos.* Peripatetic philosophy may have received its name from this custom.

Aristotle was a pupil of Plato, who felt that a person could reach the truth only by logic and reason. Plato taught that the world of *appearances* (everyday life) did not accurately represent the real world, which consisted of true ideas. Aristotle believed that reality could not be separated from appearance. He felt that to know reality, a person had to study appearances. Aristotle held that everything except pure form (God) and pure matter was a combination of both form and matter. S. Marc Cohen

Periscope, *PEHR uh skohp,* is an optical instrument with which a person can observe objects from a distance or when vision would normally be blocked. In its simplest form, the periscope consists of a long tube with a reflecting mirror or prism at each end. These reflecting surfaces are exactly parallel to one another, and are arranged at an angle of 45 degrees with the axis of the tube. They normally enlarge the image.

Periscopes are important in submarines and tanks, and other weapons. Submarines can remain submerged at *periscope depth*—about 30 feet (9 meters) below the surface—while officers observe objects above the surface with the periscope. Tanks can remain closed and protected against gunfire and chemical weapons while their crews use periscopes. Periscopes enable helicopter gunships to hover behind trees or hills while the crew makes observations and shoots missiles.

Periscopes are also used in laboratories and nuclear reactors. They permit scientists and engineers to make observations without endangering themselves.

Electronic periscopes that use *optical fibers* are being developed. Such fibers can carry images long distances. See **Fiber optics.** Norman Polmar

Peritonitis, *PEHR uh tuh NY tihs,* is an inflammation of the *peritoneum,* the thin membrane that lines the abdominal cavity. It is an illness that can cause death. The peritoneum may become inflamed if it is attacked by bacteria or irritated by a foreign substance.

Peritonitis may be either *chronic* or *acute. Chronic peritonitis* lasts for a long time. It can cause inflamed tissues to grow together. As a result, the intestines may not work properly. People suffering from tuberculosis sometimes develop chronic peritonitis.

Acute peritonitis occurs suddenly. The inflammation may affect a small part of the peritoneum, or it may involve a large area. It starts with fever, chills, vomiting, and severe abdominal pain. The abdomen becomes rigid and swells. The pulse becomes rapid, and the number of white blood cells increases.

Acute peritonitis is caused by bacteria that escape from such organs of the body as the alimentary canal, fallopian tubes, or pancreas. Bacteria can escape from an organ such as the appendix if the organ is so badly infected that it tears open. This may follow such conditions as gangrene of the intestine, a damaged bowel, or an infected pancreas.

Peritonitis requires prompt medical care. Antibiotics and other drugs are used to treat any infection and control pain. If an organ breaks open, an operation is usually performed as soon as possible to close the opening and drain the infection. Andrew G. Plaut

:rlman, Itzhak, *EETS zhahk* (1945-), is a noted aeli violinist. He is known for his rich tone, his techni- mastery, and the joy and warmth he communicates in playing.

Perlman was born in Tel Aviv. In 1958, he was a winner an Israeli talent competition. Perlman and other win- rs traveled to the United States to tour and appear on evision. He remained after the tour and continued his ısical training at the Juilliard School in New York City. 1963, he made his professional debut at Carnegie Hall New York City. In 1964, he won the Leventritt Compe- ɔn, a contest among young musicians. This victory led concert performances all over the world.

Perlman contracted polio at age 4, and his legs be- came permanently paralyzed. He walks with crutches and performs seated. Perlman actively promotes laws to ease the access of disabled people to buildings and transportation. Stephen Clapp

Permafrost is ground that remains frozen for two or more years. Such ground may consist of rock, sand, or soil. Usually, ice surrounds this material, binding it into a solid mass. *Dry permafrost* occurs in rock and gravel where there is little ice. Permafrost may be *continuous* or *discontinuous.* Continuous permafrost occurs where the mean annual air temperature remains below 18°F (- 8°C). Discontinuous permafrost has areas of unfrozen land within larger, permanently frozen areas.

Permafrost in the Northern Hemisphere

WORLD BOOK map

Permafrost underlies about a fourth of the world's land. In Canada, it underlies about half the land. In Canada and Russia above the Arctic Circle, the ground is frozen to depths up to 5,000 feet (1,500 meters).

In summer, soils thaw in an *active layer* above the per- mafrost. The depth of this layer ranges from 8 to 25 inch- es (20 to 64 centimeters) in *peat* (partly decayed plant matter) and from 20 to 110 inches (50 to 280 centimeters) in sand and gravel. Heat from buildings, roads, railways, pipelines, and other structures may thaw massive amounts of ice in permafrost, often causing damage to these structures. Lawrence C. Bliss

Permalloy, *PUR muh loy,* is a nickel-iron alloy that is easy to magnetize. It can be magnetized by wrapping an insulated wire around it and sending an electric current through the wire. Permalloy loses its magnetism when the current is turned off. When a weak alternating cur- rent is sent through a coil wound around a Permalloy bar, it produces a strong magnetic field in the material. For this reason, Permalloy is an ideal material for use as

the core of the low-power inductors and transformers used in communication engineering. The term *Permalloy* comes from the two words *permanent* and *alloy.* Permalloy was developed in 1916 by G. W. Elmen, an engineer for the Western Electric Company. Today, scientists are developing new alloys that have better magnetic properties than Permalloy. I. Melvin Bernstein

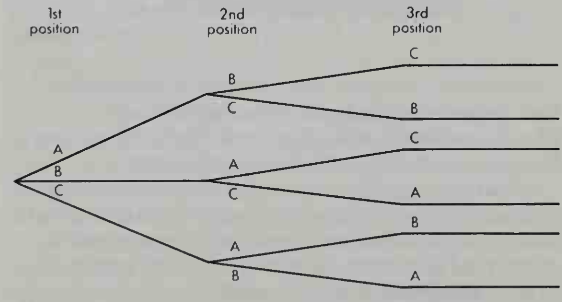
Permutations and combinations are names that mathematicians use for certain groups of objects or symbols. *Permutations* are *ordered arrangements* of a set of objects. For example, ABC, ACB, and BAC are three permutations of the set of symbols A, B, and C. *Combinations* are those groups that include the same objects *regardless of the order in which they are arranged.* The sets ABC, ACB, and BAC are all examples of the same combination. Sets such as ABC, ABD, and ACD are examples of different combinations.

The branch of mathematics that includes permutations and combinations is called *combinatorics.* Combinatorics has many uses, including the routing of telephone calls through cables and the scheduling of production in factories. It has become an area of active research as computers have grown in importance.



Counting permutations

The question, "How many sets of letters can be formed from the three letters A, B, and C?" is the same as the question, "How many permutations are there of 3 objects taken 3 at a time?" You can find the answer (1) by making a list of all the possibilities, (2) by reasoning, and (3) by using mathematical formulas.

By listing. To find the answer by listing, you merely write down all the possibilities and count them. The list below shows there are 6 possibilities. Therefore there are 6 *permutations* of 3 objects taken 3 at a time.

ABC	**BAC**	**CAB**
ACB	**BCA**	**CBA**

You could also list the possibilities in the form of a tree diagram that shows the choices for each position:

The diagram again shows that you can form 6 sets.

By reasoning. You could also find the number of permutations by reasoning. For the first position, you have 3 possible choices, A or B or C. With each of these choices, you have only 2 possible choices left for the second position, and $3 \times 2 = 6$. With each of these 6, you have 1 possible choice for the third position, and $6 \times 1 = 6$. Therefore, the number of possible sets of letters is $3 \times 2 \times 1 = 6$.

Using reason is better than just listing the permutations because reasoning accounts for every possibility. In listing, you might forget to include some possibilitie especially if you had a large number of objects.

Suppose, for example, that you had 26 letters instead of only the letters A, B, and C, and that you were asked to find the total number of sets of *3* letters that could be formed. Listing all the possibilities would be difficult and tedious. But finding the answer by reasoning woul be easy. With every one of the 26 possible choices for the first position, there would be 25 choices for the sec ond position. This makes a total of 650 possibilities ($26 \times 25 = 650$). With each of these 650 choices, there would be 24 letters remaining as possible choices for the third position, making a total of 15,600 possible con binations ($650 \times 24 = 15{,}600$). The total number of permutations is therefore $26 \times 25 \times 24 = 15{,}600$.

The above example illustrates the *multiplication prin ciple* for permutations: *If the first position can be filled in* n *ways, and the second can be filled in* n-1 *ways, an the third in* n-2 *ways, then the total number of permuta tions in the three positions is* n × (n-1) × (n-2).

Suppose you had only A's, B's, and C's, but at least *3* of each. How many sets of 3 initials could you form? (The sets would include AAA, AAB, ABB, and so on.) In this example, each position could be filled in 3 differen ways, and so you could calculate the answer: $3 \times 3 \times$: $= 27$ sets. With 26 letters and at least 3 of each, you could form $26 \times 26 \times 26 = 17{,}576$ sets.

By using symbols and formulas. In mathematical terms, the number of permutations of n things taken r a time is represented by the symbol P^n_r (sometimes wri ten ${}_nP_r$). Using this symbol, you can express the answe to permutation problems as follows:

3 things (such as A, B, and C) taken 3 at a time

$$P^3_3 = 3 \times 2 \times 1 = 6$$

26 things taken 3 at a time

$$P^{26}_3 = 26 \times 25 \times 24 = 15{,}600$$

n things taken r at a time

$$P^n_r = n(n-1)(n-2)\ldots[n-(r-1)]$$

The last expression is the general formula. The brac eted quantity, $[n-(r-1)]$, means n minus the quantit $(r-1)$. Algebraically, this quantity is the same as $(n -$ $+ 1)$. This quantity tells you at what point to stop writir successive multipliers in the formula. For example, if n 26 and r is 3, then $(n - r + 1) = 26 - 3 + 1 = 24$ and so the multipliers for P^{26}_3 are $26 \times 25 \times 24$.

Solving combination problems

If you had 4 books, how many sets of 3 books could you form? This question is the same as the question, "How many *combinations* are there of 4 things taken 3 a time?" Suppose, for example, that the 4 books were written respectively by Adams, Beery, Cole, and Doe. I you chose books by Adams, Beery, and Cole, your rea ing material would be the same regardless of the ord in which you read the books. Thus, there is only 1 *con bination* of these 3 books taken 3 at a time. How many other 3-book combinations could you make from the books? As in the permutation problem above, you ca find the answer (1) by listing the possibilities, (2) by re soning, and (3) by using mathematical formulas.

By listing. For simplicity, represent the 4 books by

e letters A, B, C, and D. Write down several groups of ese 4 letters, and then cross out one letter at a time, al-ays leaving a group of 3. You would cross out a differ-it letter each time so that the remaining group would ways be a different combination.

ABC~~D~~ ⟶ ABC
AB~~C~~D ⟶ ABD
A~~B~~CD ⟶ ACD
~~A~~BCD ⟶ BCD

ie list shows that there are 4 possible combinations.

By reasoning. A knowledge of permutations enables ›u to arrive at the answer in the following way. You can :lect any 3 of the books in 6 different orders, for exam-e, ABC, ACB, BAC, BCA, CAB, CBA. But these 6 *permu-tions* represent only a single *combination.* You can onclude that there are 6 permutations for *each* differ-it combination of 3 books. Therefore, the total number permutations must be equal to 6 times the number of ›ssible combinations. Likewise, the number of possi-e combinations must be equal to the total number of ermutations divided by 6. The total number of permu-tions of 4 books taken 3 at a time is

$$P_3^4 = 4 \times 3 \times 2 = 24$$

The number of permutations for each combination of books is

$$P_3^3 = 3 \times 2 \times 1 = 6$$

Therefore, the number of possible combinations is $4 \div 6 = 4$.

Suppose you want to count how many combinations 3 different letters could be in a spoonful of alphabet ›up. In the section of this article on counting permuta-›ns, we calculated that the total number of permuta-›ns of 26 letters taken 3 at a time is $26 \times 25 \times 24 =$;,600. We also calculated that the number of permuta-›ns for each combination of 3 letters is $3 \times 2 \times 1 = 6$. ierefore, the number of possible combinations in our ›oonful of soup is $15{,}600 \div 6 = 2{,}600$.

By using symbols and formulas. The number of ›mbinations of n objects taken r at a time is repre-›nted by the symbol C_r^n (sometimes written $\binom{n}{r}$ or ${}_nC_r$). ı the book example, the number of possible combina-›ns can be expressed and calculated as follows:

$$C_3^4 = \frac{P_3^4}{P_3^3} = \frac{4 \times 3 \times 2}{3 \times 2 \times 1} = \frac{24}{6} = 4$$

he general formula for combinations is

$$C_r^n = \frac{P_r^n}{P_r^r} = \frac{n(n-1)(n-2)\ldots(n-r+1)}{r(r-1)(r-2)\ldots 3 \times 2 \times 1}$$

›r example, if $n=6$ and $r=4$,

$$C_4^6 = \frac{6 \times 5 \times 4 \times 3}{4 \times 3 \times 2 \times 1} = 15$$

Mathematicians simplify the formula for C_r^n by using *ctorial notation* to represent the product of a positive hole number with all the positive whole numbers less ıan itself. *Factorial 3* means $3 \times 2 \times 1$, and it is written . Likewise, 4! means $4 \times 3 \times 2 \times 1$. Permutation for-ıulas can therefore be simplified as follows:

$$P_3^3 = 3! \qquad P_4^4 = 4! \qquad P_r^r = r!$$

The simplified combination formula is

$$C_r^n = \frac{n(n-1)(n-2)\ldots(n-r+1)}{r!}$$

Mathematicians simplify the above formula even more and write it as follows:

$$C_r^n = \frac{n!}{r!(n-r)!}$$

The last two formulas are the same because

$$\frac{n!}{r!(n-r)!} =$$

$$\frac{n(n-1)(n-2)\ldots(n-r+1)(n-r)(n-r-1)}{r!(n-r)(n-r-1)} \cdot \frac{(n-r-2)\ldots 3 \times 2 \times 1}{(n-r-2)\ldots 3 \times 2 \times 1}$$

All factors in this expression can be divided out except for $n(n-1)(n-2)\ldots(n-r+1)$ in the numerator and $r!$ in the denominator. These are the same factors that appear in the original combination formula.

With the two forms of the combination formula, you can calculate the number of possible combinations in two ways. For example, if you had 5 books from which to choose a set of 3, you could find the number of combinations as follows:

$$C_3^5 = \frac{5 \times 4 \times 3}{3 \times 2 \times 1} = 10$$

$$C_3^5 = \frac{5 \times 4 \times 3 \times 2 \times 1}{(3 \times 2 \times 1)(2 \times 1)} = 10$$

If you divide out factors in the numerator and denominator of the above expressions, you will see that they are identical. See also **Factor.**

History

The real development of mathematical thought about permutations began in the 1600's with the development of the theory of probability. About this time, the French mathematician Blaise Pascal discovered an interesting device for computing combinations. The device, called the *Pascal triangle,* is shown in the illustration. Pascal constructed the triangle so that each number was the sum of the two numbers above it. The numbers, called elements, are arranged in *rows.* Each element has a *place* in a row determined by counting from left to right. Thus, 20 appears in the 4th place of the 7th row of the triangle.

Pascal found that the element in the $(r+1)$th place of the $(n+1)$th row is the same as the number of combinations of n things taken r at a time (C_r^n). If n is 6 and r is 2, the number of combinations is given in the 7th row, the 3rd place (15, as circled). But 15 also appears in the 5th place of the 7th row (dashed circle). Because the triangle is sym-

1 2 1
1 3 3 1
1 4 6 4 1
1 5 10 10 5 1

metrical, the element that is in the $(r+1)$th place of the $(n+1)$th row is always the same as the element in the $(n-r+1)$th place of that row. Therefore, $C^n_r = C^n_{n-r}$. For example, if n is 6 and r is 2, the same number of combinations is possible if the objects are taken 2 or 4 at a time. Thomas J. Brieske

Perón, *pay ROHN,* **Eva Duarte de,** *AY vah DWAHR tay day* (1919-1952), was the second wife of President Juan Perón of Argentina. Eva, also called Evita, helped Perón rise to power and became one of the most famous women of her day.

Eva Perón was born Maria Eva Duarte in Los Toldos near Buenos Aires. Her family was poor, and she went to Buenos Aires at the age of 15 to become an actress. She met Perón in 1944 when she was a successful radio actress, and married him in 1945. In 1946, he became president of Argentina. Eva began to serve as his contact with the country's labor unions. In 1948, she established a women's branch of Perón's political party.

In 1951, Eva tried to join her husband in the government by running for vice president. But leading Argentine military officers feared that in time she might succeed to the presidency, and they blocked her candidacy. The officers opposed her mainly because they could not accept the idea of a woman becoming the nation's president and top military commander. Eva died of cancer in 1952. Marysa Navarro

Perón, *pay ROHN,* **Juan Domingo,** *hwahn doh MEENG goh* (1895-1974), was president of Argentina from 1946 to 1955, and again in 1973 and 1974. He ruled as a military dictator but was idolized by Argentina's workers and was probably the most powerful leader in Argentine history.

Perón was born in Lobos, Argentina. He first shared control of the government after a revolution in June 1943. He held three cabinet posts in the government of President Pedro Ramírez. Perón's reform programs as secretary of labor and social welfare won him the support of labor. He also gained strength from the backing of the army. However, many military officers distrusted Perón. In October 1945, they forced him to resign and had him arrested. Organized labor held mass protest demonstrations, and Perón was soon released.

Perón was elected president of Argentina in 1946. His second wife, Eva Duarte de Perón, helped him rise to power. She died in 1952. See **Perón, Eva Duarte de.**

Perón aimed to make Argentina the leading political financial, and military power of Latin America. He was one of the first leaders to outline the "third position," a policy of refusing to support either the Communist or the non-Communist *bloc* (group of nations).

Perón used press censorship and other violations of civil rights to control his opposition. In 1955, the Roma Catholic Church broke with Perón after he had challenged its authority and had legalized divorce and pro titution. In September 1955, the army and navy revolte and forced Perón to resign. Perón moved to Spain, but his followers, called *Peronistas,* remained active.

The Peronistas gained strength during the late 1960 and early 1970's, a period of economic problems in Ar gentina. In 1973, Perón returned to Argentina and was elected president. His third wife, Isabel Martinez de Perón, was elected vice president. Perón died in 1974, and his wife succeeded him. Military leaders deposed her in 1976. Perot, *puh ROH,* **Ross** (1930-), is an American businessman who became an independent candidate for president of the United States in 1992 and 1996. A billionaire, Perot gained widespread support even though he had little political experience.

Many people supported Perot's candidacies for pre dent because they considered him a political "outside with no commitments to powerful interest groups. Some voters thought Perot's business background would make him an effective president.

In February 1992, Perot had promised to run for pre dent if his name were placed on ballots in all 50 states before the November 1992 election. But in July, he announced that he would not seek the presidency, statir he did not believe he could win enough votes to be elected. Nevertheless, campaign workers later succeeded in putting his name on all the states' ballots. Then, in October, Perot announced his candidacy for the presidency. Perot chose as his running mate Jame B. Stockdale, a retired United States Navy vice admira Perot received about a fifth of the popular vote in the election, which was won by the Democratic candidat Governor Bill Clinton of Arkansas.

In 1996, Perot became the presidential nominee of e Reform Party, which he had founded. He chose economist Pat Choate as his running mate. Perot finished third in the election, which was won by President Clinton, the Democratic candidate. Senator Robert J. Dole of Kansas, who was the Republican nominee, was the runner-up.

'erpetual motion machine is a hypothetical deice that can continuously produce work with no energy nput, continuously convert energy completely into vork, or continuously produce more energy than it conumes. No one has ever succeeded in building a perpetal motion machine, and almost all scientists and engieers believe no one ever will.

For a machine to achieve perpetual motion, it would ave to violate one or both of two *laws of thermodynamics.* These laws summarize how machines work. The first law states that energy cannot be created or destroyed. Energy may change form—for example, from internal energy to mechanical motion—but the total energy of any *system* remains the same. A system may be anything from a simple object to a complex machine. The second law says that heat, by itself, can flow only from a hot object to a colder object. See **Thermodynamics.**

WORLD BOOK illustrations by Zorica Dabich

'erpetual motion machines are supposed to run forever, but o one has succeeded in inventing such a device. In the overbalnced wheel, *top,* each descending ball is farther from the ceni and exerts more force than each ascending ball. But because iere are more ascending balls, the wheel does not turn. The nagnetic machine, *bottom,* also does not work. Any magnet that an pull a ball up the ramp will not let it go back down.

Inventors have proposed at least two kinds of perpetual motion machines. The first kind would run forever with no energy input. The second kind would continuously convert energy completely into work. A machine that would continuously yield more energy than it consumes is considered by some experts to be a third type of perpetual motion machine. Other experts class this device with the first kind of perpetual motion machine.

The first kind of perpetual motion machine violates the first law of thermodynamics. This machine will not work, because resistance opposes the moving parts of all machines. To keep running, the machine must use energy to overcome this resistance. Without energy input, therefore, the machine soon stops.

The second type of perpetual motion machine violates the second law. This type of machine traditionally does work by exploiting the natural flow of heat from a hot region to a cooler region. But once the flow of heat has warmed the cool region to the same temperature as the hot region, the machine stops. Some inventors have proposed machines that would continuously produce work by converting all the energy of the randomly moving molecules in the sea or atmosphere. However, no machine has been able to accomplish this, either.

A machine that would continuously produce more energy than it consumed also violates the first law of thermodynamics. This machine would have to create energy.

Some people have considered artificial satellites as possible sources of perpetual motion. But atmospheric friction limits the lifetimes of artificial satellites that orbit relatively close to the earth. Scientists expect that even satellites that orbit the sun may eventually be pulled into it. Nuclear energy has also been considered a possible source of perpetual motion. Uranium and other nuclear fuels do contain tremendous amounts of energy for their size. But after this energy is used up, the remaining matter must be replaced with fresh fuel. Perrault, *peh ROH,* **Charles** (1628-1703), a French writer, is best known for a book of fairy tales he collected, *Tales of Mother Goose.* The collection, published under his son's name in 1697, includes "Sleeping Beauty," "Little Red Riding Hood," "Bluebeard," "Puss in Boots," and "Cinderella." See **Mother Goose.**

Perrault was born in Paris. He became a high-ranking civil servant and a member of the French Academy under King Louis XIV. His older brother was the famous architect and scientist Claude Perrault. Charles was known for his progressive, evolutionary view of history. He helped start a famous literary battle called "The Quarrel of the Ancients and the Moderns." In *The Century of Louis the Great* (1687) and *Parallels Between the Ancients and the Moderns* (1688), he argued that the cul-

ture of his own time was superior to the culture of classical Greece and Rome. He felt that the "Moderns" would win the battle through science, the rational philosophy of René Descartes, and progress in knowledge, culture, and literature. Robert B. Griffin

Perry, Matthew Calbraith (1794-1858), was a famous United States naval officer, best known for opening Japan to Western trade and diplomacy. Japan had virtually isolated itself from Western countries since the early 1600's. It had resisted, sometimes by force, attempts by Americans and Europeans to establish business and diplomatic ties. In 1854, Perry negotiated a treaty between Japan and the United States. This was Japan's first modern treaty with a Western nation and marked the beginning of Japan's development into a major world power.

On July 8, 1853, Perry sailed into a hostile Japan with four warships. He headed a United States expedition to begin diplomatic and trade relations with Japan and to ensure the safety of Americans shipwrecked in the country.

Perry impressed the Japanese with a show of dignified strength. He presented Japanese officials with a letter from United States President Millard Fillmore to the Japanese emperor proposing peace and friendship. On March 31, 1854, Japan entered into a treaty of peace, friendship, and trade with the United States. Perry wrote a record of the expedition, *Narrative of the Expedition of an American Squadron to the China Seas and Japan.* The record was published in 1856.

Perry was born on April 10, 1794, in Newport, Rhode Island. In 1809, Perry entered the United States Navy as a midshipman. Perry first served on the *Revenge.* This ship was commanded by Oliver Hazard Perry, Matthew's brother. Matthew fought and was wounded in the War of 1812. Perry served as executive officer on the *Cyane.* In 1820, the *Cyane* carried freed slaves to Africa in order to help establish a colony. The colony later became Liberia.

Perry became a captain in 1837 and later took command of the *Fulton II,* one of the first naval steamships. He became deeply involved in the development of the United States Naval Academy at Annapolis, Maryland. In 1839 and 1840, he directed the first school of naval gunnery, on board the *Fulton II.*

In 1843, Perry commanded the African Squadron. This squadron was set up to protect the expanding American settlements in Liberia and to help suppress the slave trade. In the Mexican War (1846-1848), Perry commanded the squadron that helped General Winfield Scott seize Veracruz, Mexico. Perry died on March 4, 1858.

Perry, Oliver Hazard (1785-1819), was a United States naval officer who became noted for his heroism during the War of 1812. At the outbreak of the war, Perry was a naval lieutenant but had no sea command. After being promoted to master commandant, he offered his services on the Great Lakes, and received command of the Lake Erie naval force.

Except for a brief period when he fought on Lake Ontario and helped capture Fort George in Canada, Perry spent the spring and summer of 1813 in Erie, Pennsylvania, outfitting all of his vessels for battle. He left Erie in August.

Perry made his headquarters at Put-in-Bay, off the Ohio shore, and on Sept. 10, 1813, sailed from there to fight the British. His fleet included nine small ships, the largest of which were the *Lawrence,* commanded by Perry, and the *Niagara,* commanded by Jesse Duncan Elliott. During the battle, the *Niagara* took little part in the fighting. The *Lawrence* suffered a large number of casualties and after $2\frac{1}{2}$ hours was disabled. Perry then rowed to the *Niagara.* Under Perry's command, the *Niagara* kept the British from boarding the *Lawrence.* Two British ships became entangled, and the *Niagara* raked them with broadsides. The British fleet of six vessels surrendered soon after Perry had taken command of the *Niagara.*

Perry then sent to General William Henry Harrison, the military commander in the West, the famous message, "We have met the enemy, and they are ours." For his victory, Perry was promoted to captain and received a gold medal and monetary rewards. The victory gave control of Lake Erie to the Americans. General Harrison was able to cross the lake and take a large part of Upper Canada. Perry helped transport the troops. He later took part in the battle around Detroit and on the Thames River in Canada.

U.S. Navy

Oliver Hazard Perry and his fleet of nine ships defeated the British in the Battle of Lake Erie during the War of 1812. This picture shows Perry rowing to the ship *Niagara* after his ship, the *Lawrence,* was disabled.

Perry was born in South Kingston, Rhode Island. At ne age of 14, he became a midshipman and served in he West Indies under his father, who was a naval offi- er. During the war with Tripoli (1801-1805), he served in ships in the Mediterranean Sea. In 1807, as a lieu- enant, Perry directed the construction of gunboats at Newport, Rhode Island. He next took command of the *Revenge,* which ran aground in a fog in 1811 and was ost. An inquiry cleared Perry of any blame for this loss because a pilot had been in charge of the ship at the ime it ran aground. In 1819, Perry took a small fleet to Venezuela on a diplomatic mission for the government. While sailing homeward along the Orinoco River after his mission, he contracted yellow fever and died.

Perry, William James (1927-), served as United States secretary of defense from 1994 to 1997, under President Bill Clinton. Perry, a mathematician, had spent much of his career working on defense technology.

Perry was born in Vandergrift, Pennsylvania. In 1946 and 1947, he was a surveyor in the United States Army Corps of Engineers. Perry received bachelor's and mas- er's degrees in mathematics from Stanford University in 1949 and 1950, respectively. He earned a Ph.D. in math rom Pennsylvania State University in 1957. From the 1950's to the 1970's, Perry worked for a number of mili- ary electronics firms. In 1964, Perry became a co- ounder of ESL, Inc., which developed electronic detec- ion systems.

Perry became a consultant to the Department of De- ense in 1967. As the department's undersecretary for re- search and engineering, from 1977 to 1981, he urged the armed forces to adopt advanced technology, including "stealth" aircraft, which are hard to detect by radar. From 1981 to 1993, Perry worked as an investment banker. He served as co-director of Stanford's Center for Interna- tional Security and Arms Control from 1989 to 1993, when he became deputy secretary of defense.

Persephone, *puhr SEHF uh nee,* was a beautiful god- dess in Greek and Roman mythology. The Greeks also called her *Kore.* The Romans called her *Proserpina.* Per- sephone was the daughter of Demeter (Ceres in Roman mythology), the goddess of agriculture and fertility. Per- sephone's father was Zeus (Jupiter), the king of the gods. An important myth describes Demeter's search for Per- sephone after the girl was kidnapped by Hades (Pluto), god of the dead.

One day, while Persephone was picking flowers in a meadow, the earth opened up. Hades seized Perseph- one and carried her to his underworld kingdom to be- come his wife. Demeter was heartbroken at the loss of her daughter. She wandered the world looking for Persephone.

Demeter became angry with the gods for allowing Persephone to be carried off. In revenge, Demeter re- fused to let crops grow. To return fertility to the earth, Zeus ordered Hades to return Persephone to her mother. But while in the underworld, Persephone had eaten seeds of the pomegranate, a fruit that symbolized marriage. By eating the seeds, she entered into a mar- riage with Hades that could not be ended.

Zeus arranged a compromise between Demeter and Hades. Persephone would spend two-thirds of each year with her mother and the remaining third with Hades. While Persephone lived with Hades, the earth became dry and barren, reflecting Demeter's unhappiness. But while Demeter and Persephone lived together, crops flourished. The myth of Persephone was used to help explain the cycle of fertility in nature. Justin M. Glenn

Persepolis, *puhr SEHP uh lihs,* was a capital of ancient Persia. King Darius I of Persia built Persepolis about 500 B.C. in a mountain region of what is now southwest Iran. Darius and his successors constructed large stone and mud-brick palaces in the capital, which became the roy- al ceremonial center for the religious holiday of the New Year. Every year at this festival, the king would re- new his divine right as king, and representatives of all the peoples within the Persian Empire would bring him gifts. In 330 B.C., Alexander the Great seized Persepolis.

Archaeologists have uncovered a large number of the ruins of Persepolis. Some of the ruins have been re- stored. Visitors may see a representation of the proces- sion of New Year's gift givers carved in stone on two grand staircases leading to the king's Audience Hall.

Perseus, *PUR see uhs,* in Greek mythology, was the son of the god Zeus and the mortal Danaë. King Acri- sius, Danaë's father, learned from an oracle that his own grandson would someday kill him. In fear, he set the in- fant Perseus and Danaë adrift in a chest. Dictys, a fisher- man, rescued them. Perseus grew to manhood in Dic- tys's home on the island of Seriphus.

King Polydectes, Dictys's brother, tried to force Danaë to marry him. To prevent the marriage, Perseus agreed to slay Medusa, a snake-haired monster called a Gorgon whose horrible face turned all who looked at her to stone. With the help of the goddess Athena, Perseus be- headed Medusa while gazing at her reflection in his shield (see **Gorgons; Medusa**).

While returning home, Perseus rescued the beautiful maiden Andromeda from a giant sea monster and mar- ried her. In Seriphus, he turned Polydectes to stone with the head of the Medusa. Perseus later accidentally killed his grandfather with a discus, fulfilling the prediction of the oracle. Nancy Felson

Perseus, *PUR see uhs,* is a constellation of the north- ern sky. It lies between the constellations of Auriga and Cassiopeia. Mirfak, the brightest star in Perseus, is larger than the sun. Perseus contains the *binary star* Algol. The pair of stars called Algol periodically eclipse each other, so that Algol appears alternately fainter and brighter (see **Algol**). In Greek mythology, Perseus won this place among the stars for cutting off the head of the monster Medusa. See also **Constellation.** Sumner Starrfield

Pershing, *PUR shihng,* **John Joseph** (1860-1948), commanded the American Expeditionary Forces (A.E.F.) in Europe in World War I (1914-1918). The A.E.F. was the first United States army ever sent to Europe. Pershing trained and led in battle an army that grew within 18 months from a small group of regulars to almost 2 mil- lion men. After the war, he received the highest rank ever given an American Army officer, General of the Armies of the United States. But Congress granted the same title to George Washington in 1976, so that no

other general, past or present, would outrank him.

Teacher-soldier. Pershing was born near Laclede, Missouri. He began to teach in a local black school at age 17.

Pershing graduated from the U.S. Military Academy in 1886 and began active service by fighting against the Apache. While serving as military instructor at the University of Nebraska, Pershing earned a law degree.

Pershing was teaching tactics at the U.S. Military Academy when the Spanish-American War began in 1898. He fought with distinction as a first lieutenant with the 10th Cavalry in the Santiago campaign.

Promotion. Pershing served in the Philippines from 1899 to 1903 and directed the Mindanao Island campaign against the rebellious Moros tribe. He was still a first lieutenant at age 40 and considered resigning from the Army because of slow promotion. But he became a captain in the Philippines. His work in subduing the Moros, who had never been conquered, won the admiration of President Theodore Roosevelt.

Pershing became military attaché to the U.S. Embassy in Japan after the outbreak of the Russo-Japanese War in 1904. He went with Japanese General Tamemoto Kuroki to Manchuria, where as military observer he studied modern warfare on a large scale. He returned to the Philippines after the war. In 1906, President Roosevelt raised Pershing's rank from captain to brigadier general.

Mexican campaign. In 1916, Pershing took command of the army that entered Mexico in pursuit of Pancho Villa and his rebels. Villa's troops had raided and burned the border town of Columbus, New Mexico. Although Pershing did not capture Villa, the long pursuit made "Black Jack" Pershing (so called because he had once commanded an all-black troop) a public figure in the United States. When the United States entered World War I in 1917, he was chosen to command the A.E.F.

World War I. Upon arriving in France, Pershing laid a wreath on the tomb of the Marquis de Lafayette. One of his staff officers, Colonel Charles E. Stanton, gave a speech on Pershing's behalf. In the speech, Stanton said "Lafayette, we are here." This symbolized the repayment of aid that Lafayette and other French people had given America during the Revolutionary War.

Pershing's greatest work as commander of the American Expeditionary Forces was to preserve the unity of the American army in combat and maintain the spirit of the offensive. The Allied generals wanted to use the American troops to fill the ranks of their battered armies, but Pershing insisted that, except in certain cases, the American army should fight independently. He believed that the arrival of a large, fresh American army at the front would hurt German morale. Also, the Americans had been trained for fast, driving warfare, which Pershing believed was needed to win. Pershing opposed the slow trench warfare of the Allied armies. His theory of offensive warfare, though it cost many American lives, succeeded against the German army.

Later career. Pershing served as chief of staff of the U.S. Army from 1921 to 1924. After his retirement, he served as chairman of the American Battle Monuments Commission and in several honorary diplomatic assignments. During World War II (1939-1945), he consulted with Army Chief of Staff George C. Marshall, but took no other active part in the war. Pershing was buried in Arlington National Cemetery. Christopher R. Persia. See **Iran; Persia, Ancient.**

Persia, Ancient, was a land that included parts of what are now Iran and Afghanistan. Under Cyrus the Great, Darius I, Xerxes, and other leaders it became the home of a great civilization, and the center of a vast empire. The name *Persia* came from *Persis,* the Greek name for the region. The Persians themselves called the region the *land of the Aryans,* from which the name *Iran* comes. The Persians called their language *Aryan.*

The early Persians were nomads who came to the area around 1000 B.C. from the land that surrounds the northern part of the Caspian Sea. They were good organizers and administrators, and the empire that their descendants created lasted over 200 years. They made important contributions in government, law, and religion. The Persians developed an efficient "pony express" relay system of mail delivery, built an irrigation system, and tried to standardize weights and measures. For a quotation about their postal system, see **Postal services** (Ancient times).

The Persians treated their subjects better than earlier rulers had, and they probably influenced the actions and policies of later governments. Alexander the Great built on Persian accomplishments to unify his empire. So did the Arabs in building their civilization.

In the 500's B.C., Persia became the center of the vast Achaemenid Empire. The Achaemenid Empire extended from North Africa and southeastern Europe in the west to India in the east, and it stretched from the Gulf of Oman in the south to the Caucasus Mountains and the Syr Darya River in the north. The Persians governed an

Alexander the Great conquered the empire 331 B.C. Later, Parthians and Sassanids controlled Persia before Arabs conquered it in A.D. 641.

Way of life

The people. Persians dressed in long robes, later illed *caftans,* and wore jewelry and false hair. Most of e common people lived in mud huts, much like the its many of the country people of Iran live in today. obles and kings built large stone houses and palaces. ie ruins of some of these still stand.

The Persians adopted many of the customs of the amites, the people they had conquered. But they kept any traditions of the *nomadic* (wandering) peoples. For ample, they taught their sons to ride horses, shoot ows, and speak the truth. The Persians considered it a sgrace to lie or to be in debt.

Early Persian families formed into clans, and clans to tribes. But as the empire grew, social units larger an the family began to disappear. Persian men could ive several wives. A king could select his wives only om the six highest families. Rulers had large *harems,* here all the women in the family lived.

Language and literature. The people of ancient Persia spoke Old Persian, a language of the Indo-European mily related to the Sanskrit language of India and to odern Persian. The Persians developed a cuneiform stem of writing (see **Cuneiform**). But the cuneiform stem was used only for royal inscriptions, because w people could read it. The Persians used Aramaic, a mitic language related to Hebrew, as a written language. Aramaic was widely used in Syria, Palestine, and esopotamia then, and the Persians extended its use to dia, central Asia, and Asia Minor (now Turkey). Local languages were used in various parts of Persia.

Little is known of the literature of ancient Persia. But stories of ancient heroes still survive, probably passed along by minstrels and folk tales.

Religion. The Persians believed in gods of nature, such as the sun and sky. The people believed the gods had social powers. Mithra, the god of light, for example, controlled contracts. The Persians had no temples. They prayed and offered sacrifices on mountains.

Zoroaster (or Zarathustra), a prophet who lived sometime between 1400 and 1000 B.C., reformed the ancient religion. He preached a faith based on good thoughts, words, and deeds, emphasizing a supreme god called Ahura Mazda, "the wise spirit." Zoroaster's followers, called *Zoroastrians,* gradually spread his religion throughout Persia. The teachings of Zoroaster are found in the *Gathas,* part of a holy book known as the *Avesta.*

Art and architecture in ancient Persia was a unique mixture of Greek, Egyptian, Babylonian, and other cultures. Remains of huge royal palaces have been found that stood at Pasargadae, Persepolis, and Susa, in what is now Iran. Goblets, plates, and other objects made of gold during the Persian Empire have been found. After Alexander the Great conquered Persia, silver became popular, and many silver art objects have been found. Many museums exhibit ancient Persian textiles, rugs, and pottery.

Economy. Early Persians were farmers. They raised grain and livestock. Deserts covered much of the highland region, and the peasants developed irrigation to grow wheat, barley, oats, and vegetables. They used underground tunnels to avoid evaporation by the hot sun, and brought water as much as 100 miles (160 kilometers) from the mountains to the valleys and plains. Highland Persia had few large towns until Alexander the Great conquered it. Crafts developed after cities were founded. Pottery, weaving, and metalwork in copper,

iron, gold, and silver became important occupations. Pots and pans became more important than weapons, armor, and farming tools. Potters and weavers made clothing, pottery, and rugs for the people.

Caravans carried trade goods from many parts of th world through Persia to the Mediterranean Sea. Impor tant articles of trade included precious and semipre-cious stones, and spices. A silk route to central Asia an China was opened, probably during the 100's B.C. Trad routes from Mesopotamia to the Far East led across Pe sia, skirting the central desert.

Other routes led east to India, and north to the Cauc sus Mountains and the Black Sea. The Persians built roads between cities in their empire. The most famous of these roads was the royal road that linked Sardis in western Asia Minor to Susa near the Persian Gulf. The Persians used the roads to deliver mail swiftly by relays of horsemen.

Government

Well-organized bureaus governed the Achaemenid Empire (about 550-331 B.C.). The empire was divided int provinces called *satrapies,* each governed by an official called a *satrap.* Satraps ruled and lived like minor kings But the *king of kings,* who ruled the empire from Persia had final and absolute authority. The kings *codified* (sys tematized) the laws in various parts of the empire. Troops in the satrapies were controlled by the central government. A secret service, which the Greeks called the "eyes and ears of the king," informed the king of af-fairs throughout the empire.

Under the Parthians (155 B.C.-A.D. 225) and Sassanids (c. A.D. 224-641), Persians kept the title king of kings. Some of these Persian rulers were strong, but others were weak. Local lords exercised great powers during the Parthian period.

A powerful state church existed under the Sassanids. Priests served in important civil posts, but church and state remained separate.

History

Early civilization. The first known civilization in Per-sia was that of the Elamites, who settled the region per-haps as early as 3000 B.C. Tribes of Medes and Persians wandered into Persia around 1000 B.C. The Medes cre-ated the first state on the Persian plateau about 700 B.C., and reached the height of their power in the late 600's B.C. The Persians, led by Cyrus the Great, overthrew the Medes about 550 B.C.

The Achaemenid Empire. Cyrus enlarged the Me-dian empire by seizing the kingdom of Lydia around 54 B.C. and gradually absorbing Greek colonies in Ionia, in western Asia Minor. He called this the Achaemenid Em-pire, after his ancestor, Achaemenes. He conquered Babylonia in 539 B.C. and freed the Jews in captivity there. They returned to Palestine. Cyrus was killed in 53 B.C. He had created an empire that extended from the Mediterranean Sea and western Asia Minor to the upper Indus River in what is now northern Pakistan, and from the Gulf of Oman to the Aral Sea.

Cambyses, Cyrus' son, conquered Egypt in 525 B.C., but died on his way back to Persia. A civil war for con-trol of the empire followed, and Darius I, a relative of Cambyses, became king in 522 B.C.

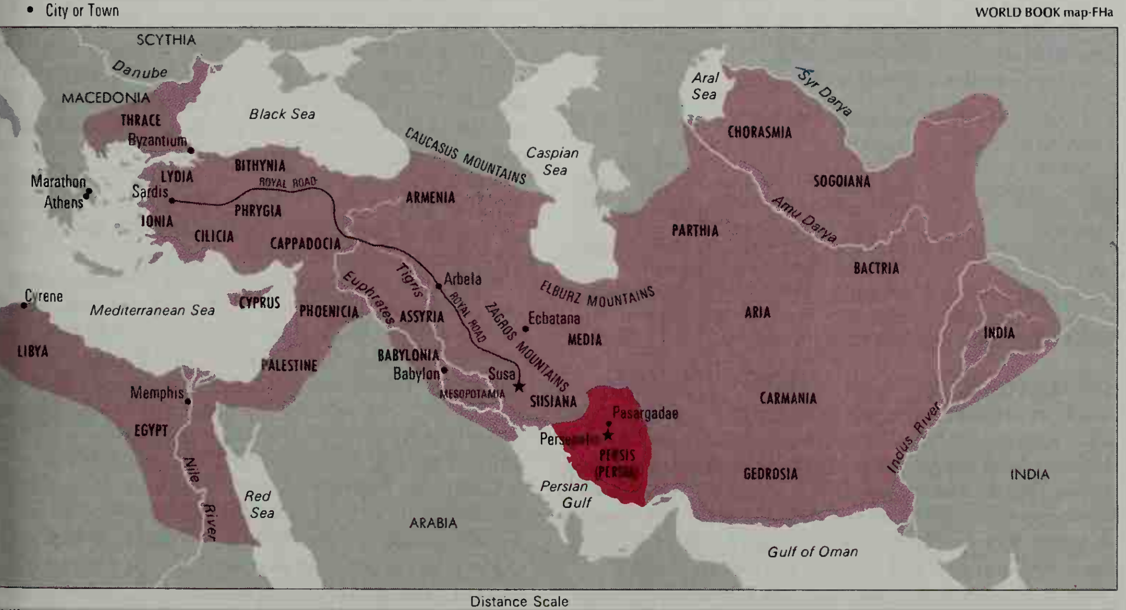
Darius reorganized the government under the satrapy ystem, established the absolute power of the king of ings, and developed a regulated system of taxation. He lso built palaces at Persepolis and Susa, two of his capals. He expanded the Persian Empire into southeastern urope and into what is now southern Pakistan.

About 513 B.C., the Persians invaded the area west and north of the Black Sea, but they did not conquer much land. Darius sent an army into Greece in 490 B.C., but it was defeated by Athenian forces at Marathon. Darius died in 486 B.C., while preparing for new attacks on Greece.

Xerxes, Darius' son, invaded Greece in 480 B.C., and defeated a force of Spartans and other Greeks after a fierce battle at Thermopylae. But the Persians suffered crushing defeats at Salamis and Plataea, and were driven from Europe in 479 B.C. See **Greece, Ancient** (The Persian Wars).



After Xerxes' death, Persia declined. But the empire continued to exist in spite of revolts until 331 B.C., when Alexander the Great defeated a huge Persian army at the Battle of Arbela (sometimes called the Battle of Gaugam-

ersian Empire about 500 B.C.

ela). This ended the Achaemenid Empire, and Persia became part of Alexander's empire.

The Seleucid dynasty. More than 10 years after Alexander's death in 323 B.C., one of his generals, Seleucus, started a dynasty that ruled Persia and nearby areas. The Seleucids founded many cities and introduced Greek culture into western and central Asia. In about 250 B.C., the Parthians won control of Persia.

The Parthian Empire lasted until about A.D. 224. The Parthians built a large empire across eastern Asia Minor and southwest Asia. During the last 200 years of their rule, the Parthians had to fight the Romans in the west and the Kushans in what is now Afghanistan. Civil wars erupted in the Parthian Empire.

In about A.D. 224, a Persian named Ardashir overthrew the Parthians and seized the Parthian Empire. After more than 550 years under other rulers, Persians again ruled Persia.

The Sassanid dynasty, named for Sassan, grandfather of Ardashir, ruled Persia until the mid-600's. Wars between Persians and Romans continued through much of the Sassanian reign. After the Romans adopted Christianity in the 300's, the conflict seemed to become a religious struggle between Christianity and Zoroastrianism, the religion of the Persians.

The Sassanian civilization reached its high point in the mid-500's. Persians won several victories over the Romans, and reconquered land that had been part of the Achaemenid Empire. Persian troops advanced to the walls of Constantinople (now Istanbul, Turkey), then the capital of the Byzantine (East Roman) Empire. But they were defeated there and forced to withdraw from all the land they had conquered.

The rise of Islam, a new religion in Arabia, brought a sudden end to the Sassanid dynasty in the mid-600's. Arabs invaded Persia and defeated the Persians in 637 and during the 640's. Islam spread across the Persian plateau. But the new Islamic rulers kept much of Persia's organization, art and architecture, and culture.

Persian Gulf, *PUR zhuhn,* is a kidney-shaped body of water in southwestern Asia between Iran and the Arabian Peninsula. Arabs call it the *Arabian Gulf.* The Strait of Hormuz links the gulf to the Gulf of Oman, an arm of the Indian Ocean. The Persian Gulf is about 500 miles (800 kilometers) long and averages 125 miles (201 kilometers) in width. It covers about 100,000 square miles (260,000 square kilometers) and is about 300 feet (91 meters) deep at the deepest point. Such sea animals as oysters and shrimp thrive in the gulf.

The gulf is bordered by Iran, Iraq, Kuwait, Saudi Arabia, Bahrain, Qatar, the United Arab Emirates, and Oman. The leading ports include Bandar-e Abbas, Bushehr, and Abadan in Iran; Al Basrah in Iraq; and Kuwait, Dhahran, Doha, Abu Dhabi, and Dubayy (also spelled Dubai) on the Arabian coast.

Persian Gulf

WORLD BOOK map

The gulf region has more than half the world's proved reserves of petroleum and natural gas. Oil and gas from the region power much of the world's industry and earn the gulf states billions of dollars each year.

In ancient times, most towns along the Persian Gulf were self-governing city-states that thrived as ports and trading centers. During the 1800's, the United Kingdom (U.K.) gained influence over much of the region. Some gulf states gained independence in the early 1900's. But the U.K. kept control over the defense and foreign affairs of the rest. By 1971, all of the gulf states were independent, and the U.K. withdrew completely from the area.

During the 1980's, the Persian Gulf was the center of much fighting in a war between Iran and Iraq. It was also the center of fighting in the Persian Gulf War (1991). During the Persian Gulf War, Iraqi troops poured millions of gallons of crude oil into the gulf, causing harm to the body of water (see **Persian Gulf War**).

'ersian Gulf War, sometimes called *Operation Desert Storm,* was fought in early 1991 between Iraq ınd a coalition of 39 countries organized mainly by the Jnited States and the United Nations (UN). The war took ›lace chiefly in Iraq and the tiny oil-rich nation of Kuvait. These two countries lie together at the northern :nd of the Persian Gulf. Leading members of the coaliion against Iraq included Egypt, France, Great Britain, ›audi Arabia, Syria, and the United States.

The coalition had formed after Iraq invaded Kuwait on \ug. 2, 1990. Iraq's invasion followed unsuccessful atempts to resolve several disputes between the two :ountries. After quickly gaining control of Kuwait, Iraq noved huge numbers of troops to Kuwait's border with ›audi Arabia, triggering fears that Iraq would invade ›audi Arabia next. Iraq's actions were viewed with alarm ›y the world's industrialized countries, which relied on (uwait and Saudi Arabia as a primary source of petroeum. A number of coalition members sent troops to ›audi Arabia to protect it from possible attack.

On Jan. 17, 1991, after months of pressuring Iraq to eave Kuwait, the coalition began bombing Iraqi military nd industrial targets. In late February, the coalition aunched a massive ground attack into Kuwait and outhern Iraq and quickly defeated the Iraqis. Coalition nilitary operations ended on February 28.

The war resulted in immense human suffering in the Aiddle East and enormous material damage in Iraq and Kuwait. Hundreds of thousands of people were killed or wounded or became refugees. Economic measures taken against Iraq caused great hardship in that nation and in other countries in the region. The war also caused severe environmental pollution in the region, as the Iraqis set hundreds of Kuwaiti oil wells on fire and dumped huge amounts of Kuwaiti oil into the Persian Gulf. In addition, the war triggered bloody revolts in Iraq by Kurds and Shiite Muslim Arabs.

April 11 The UN Security Council officially declared an end to the war.

The Persian Gulf War was the first major international crisis after the end of the Cold War (see **Cold War**). It severely tested cooperation between the United States and the Soviet Union, as well as the ability of the UN to play a leading role in world affairs. The war also split the Arab world between coalition members and supporters of Iraq's president, Saddam Hussein.

Background to the war

Competition for Arab leadership. Saddam Hussein's ambition for power and leadership in the Organization of Petroleum Exporting Countries (OPEC) and in the Middle East was a central cause of the invasion of Kuwait. Besides Iraq, OPEC members also included Kuwait and Saudi Arabia. Like those countries, Iraq was a major oil-exporting nation. But from 1980 to 1988, Iraq had fought a drawn-out war with its neighbor Iran. Iraq suffered serious economic damage in the Iran-Iraq War. Nevertheless, it emerged from that conflict as the second-strongest military power in the Middle East. Only the Jewish state of Israel was stronger.

Hussein argued that Iraq had become the region's chief power opposed to Israel and should thus be recognized by other Arab countries as leader of the Arab world. Since the late 1940's, Arab countries had fought several wars with Israel. Many Arabs wanted to abolish Israel and place its lands under the control of Palestinians and other Arabs.

Hussein claimed that, as leader of the Arab world, Iraq should receive help from other Arab countries in rebuilding its economy. According to Hussein, Iraq needed help from OPEC in raising world oil prices, along with the cancellation of debts that Iraq had incurred to Kuwait and other Arab countries to fight the Iran-Iraq War.

Disputes between Iraq and Kuwait. After the Iran-Iraq War, Hussein had disagreed with Kuwait's leaders over how much debt-cancellation and other financial ai Kuwait should provide for Iraq's economic recovery. Hussein also accused Kuwait of exceeding oil production limits set by OPEC and thus lowering world oil prices. In addition, Hussein claimed that Kuwait was tak ing Iraqi oil from the Rumaila oil field, a large field that lay beneath both Iraq and Kuwait.

Also, Iraq had often claimed that Kuwait should be part of Iraq. Iraq based its claim on the fact that, in the late 1800's and early 1900's, Kuwait had been included ir a province of the Ottoman Empire, called Basra, which later became part of Iraq. But by the time Iraq was formed in the early 1920's, Kuwait was no longer part of the province. Also by the early 1920's, Britain had gainec control of Kuwait and what became Iraq. Iraq became a independent nation in 1932, and Kuwait in 1961. But Irac did not recognize Kuwait's independence until 1963. After 1963, disputes continued between Kuwait and Iraq over the location of the two countries' common border.

What Hussein hoped to gain by taking Kuwait. Saddam Hussein was encouraged by a number of factors to consider an invasion of Kuwait. For example, by seizing Kuwait, Iraq could acquire that country's oil wealth and eliminate the Iraqi debt to Kuwait. Also, Iraq's control of Kuwaiti oil could have greatly increasec Iraq's power within OPEC.

Hussein also sought better access to the Persian Gulf. Iraq's gulf coastline was extremely short. Kuwait's was much longer and included an excellent harbor. In addition, Hussein probably hoped that an invasion would keep Iraq's military occupied and so end a series of attempts by the military to force him out of power.

WORLD BOOK map

The Persian Gulf War was fought mainly by air and land forces in Iraq, Kuwait, and Saudi Arabia and by naval forces in the Persian Gulf. Iraq also launched missile attacks against Israel. Most ground fighting occurred in desert regions.

Iraq's invasion of Kuwait

At 2:00 a.m. on Aug. 2, 1990, hundreds of tanks and other Iraqi forces swept across the Kuwaiti border. Within 24 hours, Iraq had complete control of Kuwait. Thousands of Iraqi troops then moved to Kuwait's border with Saudi Arabia. To some, this movement signalec that Iraq might invade Saudi Arabia. On August 8, Iraq announced that it had annexed Kuwait.

Under international law, none of Iraq's claims against Kuwait justified its invasion of that country. The United Nations, as well as the United States and many other countries, condemned the Iraqi invasion. Hussein, however, accused the United States and other nations of following a double standard in their reaction. According tc Hussein, if these nations condemned the Iraqi invasion, they should also condemn Israel's continuing occupation of lands it had won from Arab nations in the Arab-Israeli wars. Since the 1970's, the United States had beer Israel's chief ally.

Arabs in many countries supported Iraq's invasion of Kuwait—particularly poor Arabs and Palestinians. Hussein became a hero to numerous Arabs by confronting Israel and the United States. He gained additional support from poor Arabs by calling for the redistribution of the vast wealth of Kuwait, Saudi Arabia, and certain other Arab oil-exporting nations.

The world's reaction

On August 2, at UN Headquarters in New York City, the UN Security Council issued a resolution condemn-

ıg Iraq's invasion. Soon after the invasion, U.S. Presi-

Jnited Kingdom, and the United States. Arab members
f the coalition were Bahrain, Egypt, Kuwait, Morocco,
)man, Qatar, Saudi Arabia, Syria, and the United Arab
mirates. South Korea was the only coalition member
ıat was not also a member of the UN. The Arab coun-
ies of Jordan, Libya, and Yemen opposed the involve-
ıent of non-Arab countries but did not fight against the
oalition. China and the Soviet Union, at that time the
vorld's most powerful Communist countries, did not
ɔin the coalition. But their cooperation as members of
ıe UN Security Council allowed the UN to play a lead-
ıg role in the crisis.

Measures against Iraq. On August 6, the UN Securi-
/ Council imposed an embargo that prohibited all trade
vith Iraq except for medical supplies and food in certain
ircumstances. Nearly all of Iraq's major trading partners
upported the embargo. As a result, Iraq's foreign trade
ll but ended. On August 7, the United States an-
ounced that it would send troops to the Persian Gulf to
lefend Saudi Arabia from possible attack by Iraq.

In mid-August, Iraq began detaining various foreign
itizens who had been living in Iraq or Kuwait. These
ostages included foreign diplomats in Kuwait. Hussein
ıter ordered these people moved to military and indus-
ial sites in Iraq, where they would serve as "human
hields" to discourage attacks by coalition members. By
nid-December, however, Iraq had released all the
ostages under pressure from other countries, includ-
ıg several key Arab nations.

On August 25, the UN Security Council authorized the
ıse of force to carry out the embargo against Iraq. On
Jovember 29, the council gave coalition members per-
ıission "to use all necessary means" to expel Iraq from
uwait if Iraq did not withdraw by Jan. 15, 1991. Iraq
hose to stay in Kuwait.

The opposing forces. By mid-January, the coalition
ad about 670,000 troops, 3,500 tanks, and 1,800 combat
ircraft in the Persian Gulf region. The troops came from
8 coalition members and included about 425,000
-oops from the United States. Many of the rest of the
-oops came from the United Kingdom and France and
uch Arab countries as Egypt, Saudi Arabia, and Syria.
Coalition members that did not send troops provided
quipment, supplies, or financial support. The coalition
lso had about 200 warships in the Persian Gulf region,
ıcluding 6 U.S. aircraft carriers and 2 U.S. battleships.
-aq had between 350,000 and 550,000 troops in Kuwait
nd southern Iraq, with about 4,500 tanks and 550 com-
at aircraft. It also had a small navy.

The coalition takes military action

Militarily, the coalition first tried to force Iraq to with-
raw from Kuwait by bombing Iraqi military and indus-
ial targets. But after more than five weeks of heavy
ombing, Iraq still refused to withdraw. The allies then
started a major ground attack against Iraqi forces.

Weeks of bombing by allied aircraft left much of Baghdad, Iraq's capital, in ruins. Residents of the city lacked electricity and running water during most of the war.

The air war began at 3 a.m. on Jan. 17, 1991. The coalition aimed first to destroy Iraq's ability to launch attacks. Other goals included eliminating Iraq's biological, chemical, and nuclear weapons facilities; gaining superiority over Iraq's air force; disrupting Iraq's ability to gather information about coalition forces and to communicate with its own forces; and reducing the readiness of Iraqi troops in Kuwait and southern Iraq.

Allied aircraft first bombed Baghdad, the capital of Iraq, and then attacked targets throughout Iraq and Kuwait. The allies gradually focused heavy bombing on

Iraqi troops; artillery and tanks; transportation routes; and supplies of ammunition, food, fuel, and water.

The coalition achieved many of its objectives in the air war, in part due to the use of such high-technology equipment as night-vision systems and precision-guided weapons. These weapons included extremely accurate cruise missiles launched from U.S. ships in the gulf.

Iraq's response. Iraq responded to the start of the air war by launching "Scud" missiles at populated areas in Israel and Saudi Arabia. The Scuds were crude and inaccurate by Western standards. But they terrorized the populations of targeted cities and killed a number of people in both Israel and Saudi Arabia.

Analysts believe that Iraq used the attacks on Israel to try to draw it into the war. Had Israel struck back, Iraq might have succeeded in forcing Arab countries out of the coalition by portraying the war as an Arab-Israeli conflict. However, Israel did not enter the war, thus making it much easier to keep the coalition together.

The ground war. The first major ground battle occurred at Khafji, a small Saudi Arabian coastal town near Kuwait. The Saudis had deserted the town before the war. On January 29, Iraqi troops occupied Khafji. With U.S. help, Saudi and Qatari troops recaptured the town on January 31. By late February, the air war had reduced, through casualties and desertions, the number of Iraqi troops in Kuwait and southern Iraq to about 183,000.

At about 4 a.m. on February 24, coalition forces launched a major ground attack into Iraq and Kuwait. The attack consisted of several large operations carried out at the same time. U.S. and French troops invaded Iraq from Saudi Arabia, west of Iraqi fortifications in Kuwait. They moved rapidly north into Iraq and toward the Euphrates River to cut off Iraqi supply lines and to prevent an Iraqi retreat. U.S. and British troops also crossed into Iraq from Saudi Arabia. They moved north into Iraq and then swept east to attack the Iraqi troops.

In another operation, coalition troops assaulted Iraqi forces at several points across southern Kuwait. These coalition troops consisted of U.S. marines and troops from Egypt, Kuwait, Saudi Arabia, and Syria. The troops quickly broke through Iraqi fortifications, and about 63,000 Iraqi soldiers surrendered. On February 26, Hussein ordered his troops to leave Kuwait. But by that time, the Iraqi forces had been surrounded. The coalition ended all military operations at 8 a.m. on February 28, about 100 hours after the ground attack had begun.

The war ends. Iraq accepted the terms of a formal cease-fire agreement on April 6. On April 11, the UN Security Council officially declared an end to the war. In the cease-fire agreement, Iraq promised to pay Kuwait for war damages. Iraq also agreed to the destruction of all its biological and chemical weapons, its facilities for producing such weapons, and any facilities or materials it might have for producing nuclear weapons. Iraq did not yet have nuclear weapons, but it was trying to produce them. Iraq stockpiled chemical weapons in Kuwait before the ground war, but there is no evidence that either side used chemical weapons during the war. Neither side used biological or nuclear weapons.

After the formal cease-fire, the UN continued the embargo to pressure Iraq to carry out its promises. However, Iraq stubbornly resisted complying with the terms of the cease-fire agreement.

Consequences of the war

As many as 100,000 Iraqi troops may have died as a result of the war, but some experts believe the total is much lower. Deaths of coalition troops totaled only about 370. Thousands of civilians in Iraq and Kuwait probably were also killed during the war. Many other Iraqi civilians later died as a result of wartime destruction or because of revolts triggered by Iraq's defeat.

ation systems, communication systems, and petroleum nd other industries. Coalition attacks also wiped out nuch of Iraq's ability to provide electric power and lean water. As a result, many civilians died after the war rom disease or a lack of medicine or food.

In Kuwait, Iraqi troops looted the country and damged many of Kuwait's oil wells, in most cases by setting hem on fire. In addition, Iraq dumped an estimated 465 nillion gallons (1.75 billion liters) of Kuwaiti crude oil nto the Persian Gulf, killing wildlife and causing longerm harm to the environment.

After the war, Saddam Hussein continued to rule Iraq. ut revolts broke out among Kurds in northern Iraq and, n southern Iraq, among Arabs of the Shiah division of he Muslim religion. Both groups had long opposed lussein's rule. Iraq's army swiftly put down most of the ebellions. Hundreds of thousands of Shiite Arabs then ed to Iran. Thousands of others hid in the marshlands f southern Iraq. More than a million Kurds fled to the nountains of northern Iraq and to Turkey and Iran. Tens f thousands of Kurds and Shiites were killed in the reolts or died later of disease, exposure, or hunger.

In April 1991, the United States and other coalition nembers established a safety zone in northern Iraq to rotect the Kurdish refugees from Iraqi troops. Coalition orces remained in northern Iraq until July. But coalition ircraft continued to patrol northern Iraq as part of an ffort to enforce a ban on Iraqi aircraft flights and troop novements there. In 1992, to protect the Shiite population, coalition forces imposed a ban on Iraqi aircraft lights over southern Iraq. In 1996, Iraqi troops attacked urds in northern Iraq. The United States responded vith missile attacks against Iraqi military targets.

The Persian Gulf War also focused world attention on he Arab-Israeli conflict. Following the war, the United tates renewed diplomatic efforts to resolve disputes etween Israel and the Arab countries. These efforts elped lead to the signing of several peace agreements etween Israel and the Palestine Liberation Organizaon, a group that represents Palestinian Arabs.

The war also proved that significant new forms of inernational cooperation were possible in the post-Cold Var era. Cooperation between the United States and the oviet Union, along with China's support, allowed the JN to take effective action against Iraq.

After the war, some veterans complained of physical nd psychological ailments that they believed were reated to their service. Their symptoms, sometimes reerred to together as Gulf War syndrome, included nemory loss, fatigue, and joint pain. Some people beeved that exposure to dangerous chemicals when U.S. roops destroyed a chemical weapons depot in Iraq may ave affected the troops. Others argued that the synlrome was not a single illness and that the symptoms esulted from the stress of war or other factors.

Persimmons are pulpy, edible fruits that grow on persimmon trees. The *kaki* or *Japanese persimmon, above,* has large, shiny, dark green leaves.

Persimmon is the name of more than 200 species of small trees that belong to the ebony family. Two species are grown for their pulpy, edible fruits, also called *persimmons.* They are the *kaki* or *Japanese persimmon* and the *common persimmon.* The kaki is native to central and northern China. The common persimmon is native to the southeastern United States. Both the kaki and the common persimmon are grown in the United States. The kaki is more important commercially. It has large, shiny, dark green leaves and yellowish-green flowers. The trunk is usually straight, but the branches twist.

Persimmon fruits are round or egg-shaped and range from $\frac{1}{2}$ to 2 inches (1 to 5 centimeters) in diameter. They usually are yellowish or orange but may be streaked with red. They contain a strong astringent that causes a person's mouth to pucker. A persimmon tastes best when it is so ripe that it looks wrinkled and almost spoiled. Then it has a sweet, fruity flavor. American Indians made a kind of bread by mixing persimmon pulp with crushed corn. J. Massey

Scientific classification. Persimmons belong to the ebony family, Ebenaceae. The scientific name for the common persimmon is *Diospyros virginiana.* The kaki is *D. kaki.*

Person, in grammar, is the feature of a language that shows the difference between the speaker, the person spoken to, and a person or thing spoken about. If a word stands for the speaker, it is in the *first person.* If it stands for the person spoken to, it is in the *second person.* If it stands for any other person or thing (the person or thing spoken about), it is in the *third person.* English shows person by a change in the form of a personal pronoun or verb. Nouns are third person.

Different forms of personal pronouns show person. *I* and *we* are first person. *You* is second person. *He, she, it,* and *they* are third person.

Regular verbs change form to show person only in the third person, singular, present tense. An *-s* or *-es* is added to the first (or second) person, singular, present tense, to form the third person. I *drive* is first person, you *drive* is second person, but he *drives* is third person. The most irregular verb, *be,* changes form to show person in singular, present tense as follows: I *am,* you

are, he *is.* But plural forms of *be* in the present tense are the same: we *are,* you *are,* they *are.* First and third person forms of *be* in the singular, past tense are alike: I *was* is first person; he *was* is third person. All plural and second person forms use *were:* we, they, you *were.*

Personal property is one of the two classes into which all property may be divided. The other class, called *real property,* consists of such immovable objects as land and the houses, trees, and other objects attached to land. *Personal property* includes all other kinds of property, such as furniture, livestock, and harvested crops. The transfer of personal property is easier than the transfer of real property. Real property must be transferred in writing, but personal property may be transferred orally. Joel C. Dobris

Personality is a term that has many general meanings. Sometimes the word refers to the ability to get along well socially. For example, we speak of glamour courses designed to give a person "more personality." The term also may refer to the most striking impression that an individual makes on other people. We may say, "She has a shy personality."

To a psychologist, personality is an area of study that deals with complex human behavior, including actions, emotions, and *cognitive* (thought) processes. Personality psychologists study the enduring patterns of behavior that make individuals different from one another. Personality psychologists try to learn how these patterns develop, how they are organized, and how they change.

The nature of personality

Personality types. For hundreds of years, people have tried to group the vast differences among human beings into simple units. Some of the resulting groupings divide people into personality types based on certain characteristics.

The ancient Greek physician Hippocrates divided individuals into such types as *sanguine* (cheerful) and *melancholic* (depressed). He attributed their behavioral differences to a predominance of one of the body fluids. For example, a person was cheerful if blood *(sanguis)* was the dominant influence on his or her behavior.

Some of the more recent theories about personality types have tried to associate body build and temperament. Classifications of personality types based on body measurements were developed by two psychiatrists, Ernst Kretschmer of Germany and William Sheldon of the United States.

The Swiss psychologist Carl G. Jung, who studied psychological characteristics, classified people as *introverts* or *extroverts.* Introverts are more interested in their own thoughts and feelings than in the world around them, and extroverts are the reverse. See **Extrovert; Introvert.**

The simplicity of personality-type theories is appealing, but it also limits their value. An individual's behavior is so complex, diverse, and variable that the person cannot be sorted usefully into a simple category.

Personality traits. Related to personality-type theories is the search for broad traits or dispositions to describe enduring differences among people. Personality traits are regarded as dimensions that range from high to low. For example, anxiety is a trait that varies from the greatest anxiety to the least anxiety. Most people have some degree of anxiety along the scale between the two extremes. Psychologists have studied such personality dimensions as aggressiveness, dependency, and extroversion-introversion. People differ greatly in the degree to which they show such traits.

Studies of personality traits help reveal the relationships between an individual's standing on different personality dimensions. In one type of study, for example, psychologists give people questionnaires about their attitudes. The psychologists then rate the people on psychological traits to see if there is a relationship between having certain attitudes and possessing certain traits.

Ratings and self-reports. Research on personality traits tends to rely heavily on broad ratings of personality. In self-ratings, a person indicates the degree to which he or she thinks he or she possesses certain personality characteristics. Ratings may also be obtained from teachers, or others who know the person or who have watched the person in special situations.

These judgments may be affected by many types of bias. A person may give the responses that he or she thinks are expected and socially desirable, even if they are not true. Moreover, the answers may reflect preconceptions and *stereotypes* (fixed ways of thinking), rather than an accurate description of behavior. Tests that ask a person to rate such attributes as friendliness or adjustment provide broad self-characterizations rather than detailed descriptions of behavior. Consequently, the findings of such tests may partly reveal the concepts and stereotypes that people apply to themselves and to others. These findings may not necessarily reflect the people's actual behavior outside the test.

Some techniques are designed to reduce the role of personal meanings and concepts. Other approaches deliberately seek to clarify the individual's concepts about himself or herself. These personal concepts are especially important in theories that stress the role of the self and one's image of oneself. For example, the theory of *self-actualization* developed by the American psychologist Carl R. Rogers focuses on *phenomenology*—a person's private experiences and perceptions of the self, others, and the environment.

Projective tests. Some investigators have tried to avoid the problems of relying on a person's ratings or reports about himself or herself by creating indirect clinical techniques in the form of projective tests. These methods require the person to respond to a stimulus in relation to which there are no clear guidelines and no right or wrong answers. The person may be asked how inkblots appear on the Rorschach Test. Or the person may be told to create a story about the characters in a series of pictures in the Thematic Apperception Test. Projective techniques rely on a trained clinician to interpret the test. The value of such techniques for revealing personality is controversial and is still being studied.

Freud's psychoanalytic theory. According to the Austrian physician Sigmund Freud, the personality has three parts: (1) the *id,* which represents instinctive impulses of sex and aggression; (2) the *ego,* which repre-

sents the demands of the real world; and (3) the *super-ego,* or conscience, which represents standards of behavior incorporated into the personality during childhood.

According to Freud, mental life is characterized by internal conflicts that are largely unconscious. Impulses from the id seek immediate gratification, but they conflict with the ego and the superego. When unacceptable impulses threaten to emerge, a person experiences anxiety. To reduce this anxiety, the person may use various personality defenses. The person may, for example, *displace* (transfer) his or her emotions to less threatening objects. A child who is afraid to express aggression toward his or her father may become angry at his or her pet dog instead.

Freud's ideas have had great influence on the study of personality, but they are highly controversial. Many of his ideas had to be modified by psychologists to take greater account of social and environmental variables. See **Developmental psychology.**

Personality and environment

Trait theories and psychoanalytic theories both assume that broad internal personality dispositions determine behavior in many situations. However, research on the consistency of various personality traits indicates that what people do, think, and feel may depend greatly on the specific conditions in which their behavior occurs.

People may be honest in one situation and dishonest in another. They may be passive in some situations but aggressive in other situations or with different people. Many contemporary approaches to the study of personality therefore emphasize the role of specific social experiences and environmental events in the development and modification of behavior. Psychologists following this approach study the ways people categorize situations. Regularities and irregularities in behavior are then understood in terms of the person's perception of similarities and differences among situations.

Personality development. Some psychologists have examined the effects of early experiences on later personality development. Other investigators have studied the stability of particular patterns of personality over long periods of time. Their findings suggest that such tendencies as striving to achieve may persist to some degree from childhood into adulthood. However, research has also shown that personality continues to change as a result of new experiences and modifications in the environment.

Throughout their development, people learn about themselves and their world by observing other people and events. They also learn by trying new kinds of behavior directly. The rewards and punishments they receive after trying various patterns of behavior affect their future behavior in similar situations. People also learn by observing the results of the behavior of such social models as their parents. Suppose children repeatedly see adults succeed in antisocial or criminal acts. If they see such behavior rewarded, they are more likely to copy it than if it is punished or leads to no clear consequences. Children more readily imitate models who are powerful or who reward or take care of them.

As children develop, they copy some of the behavior of many models, including their friends as well as their parents. They combine aspects of their behavior into new patterns. Through direct and observational learning and cognitive growth, they also acquire standards and values that help them regulate and evaluate their own behavior. Gradually, people develop an enormous set of potential behaviors. The particular behavior patterns they show in specific situations depend on motivational factors. See **Motivation.**

People's cognitive and social learning experiences vary as a result of the particular social and cultural conditions to which they are exposed in the home, at school, and in other environments. Personality traits may predict many important aspects of behavior. But the setting in which behavior occurs often provides the best predictions about what people will do. Thus, although extensive differences among people are found in most human actions, considerable uniformity and regularity can occur when environmental conditions are very powerful. Strong success experiences in a new situation, for example, may override the effects of past failure experiences and of personality traits in determining future reactions to that new situation.

Emotional reactions. During the course of development, we acquire intense emotional reactions to many stimuli. Events that once were neutral may become either pleasurable or painful as the result of conditioning (see **Learning** [How we learn]).

Some reactions may involve strong anxiety and can have crippling effects. For example, children who have frightening experiences with dogs may become afraid of all dogs. This fear may *generalize* (spread) even more widely to other animals and to such objects as fur coats, for example, or hair. Such fears are especially hard to unlearn because these people tend to avoid all contact with situations that provoke fear. Consequently, these people prevent themselves from having experiences that might eliminate their fear—petting harmless dogs, for example. Emotional upsets of this kind may also be acquired by observing the fear reactions of other people.

As a result of social learning, we generalize from our experiences to new but similar or related situations. But we do not generalize indiscriminately. A young boy may learn to express physical aggression in many settings, including school, play, and home. But he also learns not to be aggressive in other situations, as when visiting his grandparents.

Personality change. Research on cognitive and social learning processes is leading to new forms of psychotherapy to help people who have psychological problems. Some of these problems are the result of learning deficits. For example, some people lack fundamental academic and vocational skills, such as reading proficiency. Individuals who have inadequate relations with others need to learn essential interpersonal skills. Some people have these basic skills, but they suffer because of emotional fears and inhibitions.

Psychoanalytic therapy to change personality tends to stress insight into the history through which the problems developed. Learning methods try to change the disturbing behavior itself by carefully planned relearning and conditioning techniques. Still other forms of personality change may be achieved by creating special

environments for learning personality patterns that are more adaptive. Lawrence A. Pervin

Personnel management is a field of management that involves using workers' skills effectively and making their jobs rewarding. Nearly all large businesses and other organizations have a department responsible for personnel management. The field is also called *employee relations* or *human resources management.* In organizations that have many employees who belong to a union, personnel management is often known as *industrial relations* or *labor relations.* Its chief function in such a company is to represent the firm in contract talks and other dealings with the union.

Specialists in personnel management have a wide range of responsibilities. They interview, test, and recommend applicants to fill job openings. They organize recruiting campaigns and travel to high schools and colleges to search for promising applicants. These managers develop pay scales, systems for evaluating employee performance, and training programs to teach workers and managers new skills. They administer employee benefits, such as health insurance, life insurance, and pensions. They offer counseling to help employees solve personal or work-related problems. Personnel managers also supervise affirmative-action plans, including special recruiting and training programs for women and minority groups (see **Affirmative action**).

Development of personnel management. In the 1800's and early 1900's, personnel management was a simple activity that involved little more than hiring employees. Hiring was easy in the United States because many immigrants were competing for jobs.

Personnel management grew in complexity and importance during the mid-1900's. People began to recognize that worker morale affects productivity and that most workers need more than reasonable wages to be happy in their job. For example, employees also require recognition, a feeling of achievement, and an opportunity to participate in decisions that affect their work. Personnel managers helped meet these needs by such means as company newsletters, recreation programs, and suggestion systems. Labor unions became more powerful, and the field of industrial relations expanded greatly. The Social Security Act of 1935 also created additional responsibilities for personnel managers, who supervised the retirement and unemployment benefits established by the act.

In the 1960's and 1970's, many new federal laws directly affected the relationship between an organization and its employees. These laws included the Civil Rights Act of 1964, the Occupational Safety and Health Act of 1970, and the Employee Retirement Income Security Act of 1974 (ERISA). Organizations relied heavily on personnel managers to help them follow federal regulations regarding minority hiring, pensions, worker safety, and other matters.

Careers in personnel management. Many colleges and universities offer courses in personnel management. Students who desire a career in this field should also study such subjects as accounting, computer science, law, marketing, and psychology. The American Society for Personnel Administration, a professional association for personnel managers in the United States, sets professional standards. Daniel Quinn Mills

Perspective is a technique used by artists to give a picture the illusion of depth and distance. When observing a picture done in perspective, viewers have the impression that they are looking through a window. The sides of the picture serve as the "window frame." The scene appears to recede into the distance from a fixed point on the viewer's side of the window.

There are two major types of perspective in Western art—*aerial perspective* and *linear perspective.* Non-Western civilizations, such as those of China and India, have also developed styles of perspective. However, the Eastern styles do not produce an effect as realistic as the Western techniques.

Aerial perspective is based on the fact that light, shade, and color change with an object's distance from the viewer. For example, distant objects appear hazier and less sharp in outline than objects seen nearby. The sky also changes from a deep blue directly overhead to an increasingly lighter blue as it approaches the horizon. An artist creates aerial perspective by varying the color tones and the strength and sharpness of the picture's lines.

Linear perspective is a technique for showing distance and depth through the form, size, and position of objects. Linear perspective is based on the optical illusion that parallel lines seem to converge as they recede toward a *vanishing point.* A vanishing point is the spot at which the parallel lines appear to meet on the horizon. Linear perspective also creates the illusion of depth by making the more distant objects smaller and placing them closer together.

Artists in ancient Greece and Rome were the first to understand the principles of both aerial and linear perspective. Both techniques were largely abandoned during the Middle Ages, which began during the A.D. 400's. But perspective was rediscovered during the Renaissance, a cultural period that began in Italy during the 1300's.

Interest in perspective reached its peak in the Renaissance paintings of the 1400's and 1500's. About 1425, the Italian architect Filippo Brunelleschi painted two scenes of the city of Florence that used mathematical formulas to create perspective. His work had a great impact on Renaissance artists, who became fascinated with using perspective to achieve realism in portraying space. Leon Battista Alberti, another Italian architect, wrote *On Painting* (1435), the first scientific study of perspective. The Italian artist and scientist Leonardo da Vinci performed many experiments that explored how the eye sees objects at a distance. Samuel Y. Edgerton, Jr.

For examples of perspective in art, see **Bellini, Giovanni; Raphael; Masaccio;** and various paintings in the **Painting** article.

Perspiration, *PUR spuh RAY shuhn,* also called *sweat,* consists of water and certain dissolved substances produced by glands in the skin. Sweat glands are distrib-

ted over the entire surface of the body. But in certain reas they are larger and more concentrated. For example, there are many large sweat glands in the armpits, n the palms of the hands, and soles of the feet. The weat glands are of almost no importance in ridding the ody of waste materials. Their primary importance is to roduce perspiration when the body needs to lose heat. weating itself does not reduce body heat. But when the weat evaporates, it has a cooling effect. See **Evaporaon; Temperature, Body.**

People perspire in cool weather as well as in warm, at ght as well as during the day. When it is cool, the nall amount of sweat produced evaporates almost as oon as it is formed. This is called *insensible* perspiraon. When the weather is warm, or during strenuous excise, the sweat glands increase their production. Then rops of water accumulate on the skin and we say a peron is sweating. This is called *sensible* perspiration.

The *hypothalamus* (part of the brain which has the ody's heat-regulating center) keeps body temperature onstant. It receives impulses from warm blood and om heat receptors in the skin. It sends signals by way f the nerves to the sweat glands, which then produce weat. Nervous tension and excitement also activate the weat glands, especially in the hands and armpits.

When the water of perspiration evaporates, certain olids (urea and salts) are left on the skin. Frequent athing will keep these solids from accumulating and ogging the pores. Excess sweating in the armpits can e counteracted by applying various substances sold for is purpose. Most of these contain aluminum chloride.

Many animals do not reduce body heat in the way at human beings do. For example, a dog has sweat ands, but they are not important in reducing the body temperature. Many persons believe that a dog perspires through its mouth. But a healthy dog rarely perspires. Instead, it cools itself by panting. Nandalal Bagchi

Perth (pop. 1,244,320) is the capital and business center of the state of Western Australia. It lies along the Swan River, near the west coast of Australia. For location, see **Australia** (political map).

The main business district of Perth is on the north bank of the Swan River, 12 miles (19 kilometers) northeast of Fremantle, a port city that borders the Indian Ocean. King's Park, which is west of Perth's main business district, includes a 1,000-acre (405-hectare) area of vegetation known as *bush.*

Perth has a warm, sunny climate. Boating in the Swan River and swimming at sandy beaches along the coast are popular recreational activities. A cultural center, which includes a museum, art gallery, and reference library, is just north of the business district. A major casino complex was opened in 1985.

The major industrial plants are far from the center of the city. Refineries process bauxite, nickel, and oil from deposits in the state. Other industries include boatbuilding, tanning, and cement and steel production. Tourism is also an important economic activity.

Perth was founded in 1829 by James Stirling, a British naval officer. The city grew rapidly after settlers discovered gold east of the area in the late 1800's. During the 1960's, other mining discoveries led to further growth and much industrial expansion. Many office buildings and hotel complexes were erected in Perth during the 1980's. R. E. Cronin

A pack train of llamas transports goods in the rugged Peruvian Andes. Peru has great extremes in landscape and climate, ranging from snow-capped mountains to steaming jungles.

Peru

Peru, *puh ROO,* is the third largest country in South America. Only Brazil and Argentina cover a greater area. Peru is a land of enormous contrasts in landscape and climate. The country lies in western South America along the Pacific Ocean. The long, narrow coast consists of a desert even drier than the Sahara. Most of Peru's large cities lie in this region, including Lima (pronounced *LEE mah),* the capital and largest city. The towering, snow-capped Andes Mountains rise east of the coast and extend north and south down the entire length of the country. This region is famous for its grass-covered plateaus, crystal-clear air, and sparkling sunshine. Thick rain forests and jungles cover most of the hot, humid region east of the Andes.

More Indians live in Peru than in any other country in South America. The Indians make up nearly half of the country's people and about a fifth of the total Indian population of North and South America. The rest of Peru's population consists mainly of people of mixed Indian and white ancestry. Whites make up only a small part of the country's population.

Peru is one of the world's leading producers of copper, lead, silver, and zinc. It also ranks among the world's leading fishing countries. But most of Peru's people are poor. Many of them make a bare living farming. Other Peruvians work for low wages in the cities or are unemployed.

The ancestors of Peru's Indians include the famous Inca Indians, who built a great empire in Peru from the 1200's to the 1500's. The first white people reached the country in the 1520's, led by the Spanish adventurer Francisco Pizarro. They conquered the Inca in the 1530's and made Peru a Spanish colony. Peru declared its independence from Spain in 1821.

Government

Peru has had a number of constitutions since it became independent in 1821. The latest constitution was adopted in 1993. Each constitution declared the country to be a democratic republic. Yet dictatorships have ruled Peru many times, including during the period from 1968 to 1980. In 1968, a group of Peruvian military leaders overthrew the constitutionally elected leaders of Peru

ıd took control of the government. The military leaders ıspended the Constitution, dismissed the legislature, ıd canceled all elections. In 1980, elections were held r a new democratic civilian government, including a ·esident and a legislature. The new government re- aced the revolutionary government.

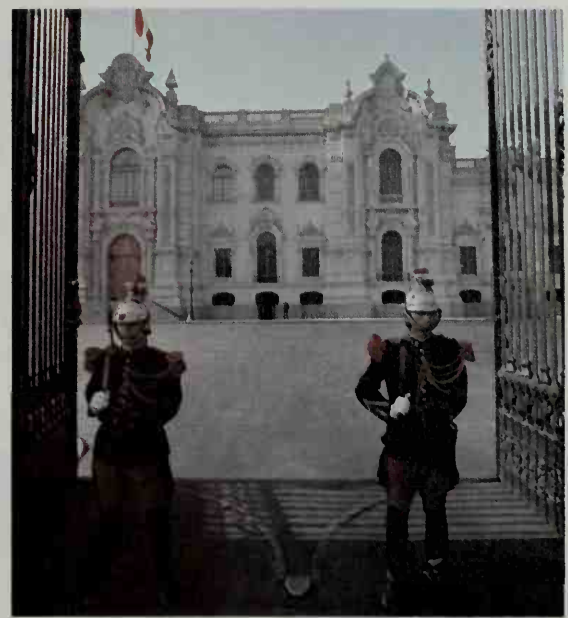
In 1992, President Alberto Fujimori suspended the ɔnstitution, dissolved the legislature, and began to rule ·ru by decree. Later that same year, a Constituent As- ·mbly was elected. The Assembly wrote a new consti- tion for Peru that took effect in December 1993. Demo- atic presidential and legislative elections took place in 95.

National government. Under the Constitution of 93, a president serves as head of state and head of the ›vernment. The president is elected by the people to a e-year term and can be reelected only once. In addi- ɔn, the people elect two vice presidents. The president points a Council of Ministers. A one-house Congress responsible for making the country's laws. The 120 embers of the Congress are elected by the people to e-year terms. The Supreme Court is Peru's highest urt.

Local government. Peru is divided into 12 regions, departments, and the constitutional province of llao. The departments are further divided into ovinces, and the provinces are divided into districts.

The armed forces—especially the army—have tradi- nally played an important role in Peruvian life. Besides ing deeply involved in politics, members of the med forces assist in such activities as police work and adbuilding.

The army, navy, and air force in Peru total about 5,000 people. The officers rank among the best- ined and best-educated officers in the world. Peru has army reserve with about 190,000 members. Military rvice is voluntary.



People

Population. A majority of the country's people live in ies or towns. Lima, which has a population of about million, is by far the largest, busiest, and most mod- n Peruvian city. Lima and the neighboring city of llao make up *Greater Lima.* Callao and the city of Are- ipa, each of which has more than 500,000 people, ık next to Lima in size. Two other cities in the country ve a population of more than 300,000. They are Trujil- and Chiclayo.

Ancestry. After the Spanish conquest of Peru in the 00's, some Spaniards and Indians married. Their de- ndants are called *mestizos.* Today, it is estimated that roximately 43 percent of all Peruvians are mestizos. proximately 46 percent of the country's people are In- ns. People of unmixed white ancestry make up about percent of the country's population. Most of these ople are of Spanish ancestry. Peru also has a small mber of blacks and people of Asian descent. These ups make up less than 1 percent of the country's pulation.

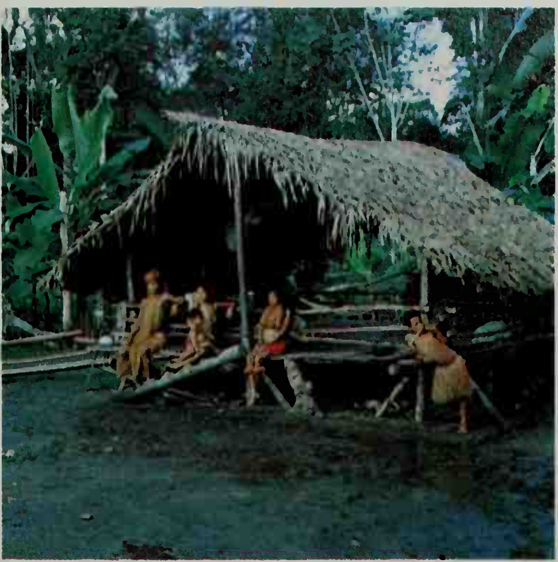
fficial language for several hundred years. In 1975, the eruvian government made Quechua, the language of ıe Inca, an official language along with Spanish.

About 75 to 80 per cent of all people in Peru speak panish. The rest speak only an Indian language. uechua is by far the most common Indian tongue. bout 2 million Indians who live in the highland reion—that is, the highest parts of the Peruvian Andes—peak only Quechua. A much smaller number of highnd Indians speak Aymara, the language of a tribe onquered by the Inca in the 1400's. In the rain forests nd jungles of eastern Peru—a region called the *selva*—cattered groups of Indians speak a variety of other trib- languages. Many Peruvians speak both Spanish and n Indian language.

Ways of life. Peru's Spanish conquerors established a rict class system that was based on ancestry. A small pper class, made up of whites, controlled a huge lower ass, made up of Indians. As the number of mestizos rew, most of them also became part of the lower class. his class system lasted until about 1900, when a small iddle class of whites and mestizos began to develop.

Peru's middle class grew steadily during the 1900's. oday, it includes office workers and managers, profesonal people, owners of small businesses, and military ficers. But the great majority of Peruvians— that is, alost all Indians and most mestizos—still belong to the wer class. Peru's small upper class still consists almost ntirely of whites.



Whites. About half of Peru's whites belong to the uper class, and about half to the middle class. A few Peruan whites belong to the lower class. The whites speak panish and dress much as people do in other Western ountries.

Family ties are important in Peruvian society. But they e especially important among upper-class white fami-s, who have traditionally controlled much of Peru's ealth. These families seldom mix with people outside eir class, and in most cases their children marry into her upper-class families. Most of the families live in shionable sections of Lima and other large cities.

Mestizos, like whites, speak Spanish and wear Western-style clothing. They have always had closer ties with e white community than Indians have had. For exame, white owners of mines and plantations traditionally red mestizos to supervise Indian workers. The growth the middle class has given mestizos other opportuni-s for advancement. Today, many middle-class mesti-s attend college and become leaders in government, dustry, the armed forces, and the professions. A few estizos have even acquired enough wealth and social anding to be accepted into the upper class. But the ajority remain in the lower class.

ven cloth. See **Clothing** (Traditional costumes).

The Indians of the selva belong to about 40 tribes. They live in scattered tribal villages, wear little clothing, and hunt and fish for most of their food.

Over the years, many Indians have moved from the highlands and selva to work on coastal plantations. Numerous other Indians have moved to the cities. But many of them have been handicapped by their lack of schooling and inability to speak Spanish.

Housing. Most rural families in Peru build their own houses. The typical house has one room. In the highlands, most houses have walls of adobe and a roof of grass thatch or handmade tile. Most homes in the selva have walls built of twigs or bamboo poles and a roof of grass or palm thatch.

Many kinds of housing can be found in Peru's large cities. In upper- and middle-class neighborhoods, the people live in comfortable single-family homes with enclosed patios. The largest cities also have high-rise apartments and modern public housing. But much urban housing in Peru is extremely poor.

Some lower-class families in Lima and other large cities live in crowded, unsanitary slums. But since the 1950's, thousands of families have left the slums and started *squatter* communities on public land on the edge of the cities. Today, more than a million Peruvians live in such communities.

Most squatters first build their home of cardboard, old metal, and other scrap. But because squatters do not pay rent, many families save enough money in time to build a permanent house of adobe or concrete block. To encourage these efforts, the government has named the squatter communities *pueblos jóvenes* (young towns) and supplied many with running water and a sewerage system.

Food. Most upper- and middle-class families in Peru eat a varied diet of meat, fish, poultry, vegetables, and

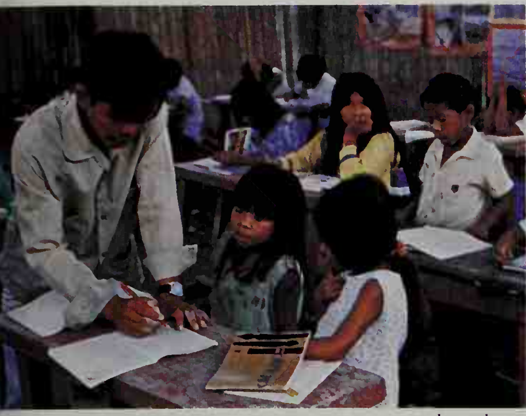
cereal products. They highly season many main dishes with onions and hot peppers. Rice, potatoes, and bread accompany most main meals.

The majority of lower-class families in Peru, especially most highland Indians, have a poor and monotonous diet. The diet of the highland Indians consists largely of potatoes, beans, corn, squash, and soups made of barley or wheat. Many highland Indians chew the leaves of the coca plant. Coca leaves contain the drug cocaine, which relieves feelings of hunger (see **Coca**). The Indians of the selva have a somewhat more varied diet. These Indians raise only a small number of crops, such as corn and *cassava,* a starchy root. However, the jungle provides the Indians of the selva with many varieties of fishes and small game and several types of fruits and nuts.

Recreation. Music and dancing are extremely popular throughout Peru. Radio stations play everything from traditional Peruvian music to the latest hit tunes from the United States. Traditional Indian music is performed on drums, flutes, rattles, and a kind of small harp. Mestizo music also uses these instruments plus such others as guitars, fiddles, and horns. Mestizo bands attract large crowds in cafes and dance halls throughout Peru. Movies are also a popular form of recreation in Peru.

Soccer, which Latin Americans call *fútbol,* ranks as the most popular sport in Peru. The country's national soccer teams play against teams from other countries in Lima's 70,000-seat National Stadium. Many Peruvians also enjoy basketball, volleyball, and bullfights.



Almost every city and town in Peru holds an annual festival, called a *feria,* to honor its patron saint. Ferias include colorful religious processions, feasting, dancing, and games. Peru celebrates the anniversary of its independence on July 28.

Education. Most Peruvians 15 years of age or older can read and write. The great majority of those who cannot read or write live in rural areas, and most are Indians. Most educated Peruvians live in the cities, which have by far the greatest number of schools. For Peru's literacy rate see **Literacy** (table: Literacy rates for selected countries).

Peruvian law requires all children between the ages of 6 and 12 to attend school. But many rural children cannot meet this requirement because of a shortage of schools and teachers. Most elementary and high school students attend free public schools. Nearly all students from middle- and upper-class families go to private schools, which charge a tuition fee. Peru has about 30 universities, including the famous University of San Marcos in Lima. Founded in 1551, it ranks as the oldest institution of higher learning in South America (see **San Marcos, University of**).

Religion. About 95 percent of all the people of Peru are Roman Catholics. However, relatively few people attend church regularly. Some Indian Catholics still worship Inca gods. The Peruvian government grants freedom of worship to all religious groups, but it officially favors the Roman Catholic religion. For example, the Catholic religion is taught in public schools throughout the country. Other religious groups in Peru include Protestants, Jews, and Buddhists.

The arts. Peru's artistic traditions date back nearly 3,000 years, when the country's Indians began to create

The Spanish colonists constructed many richly deco-ted churches and public buildings in Peru. Earth-akes have destroyed many of these structures. But me have been rebuilt. For examples of the Spanish co-nial style of architecture, see **Lima** (picture: The Plaza Armas).

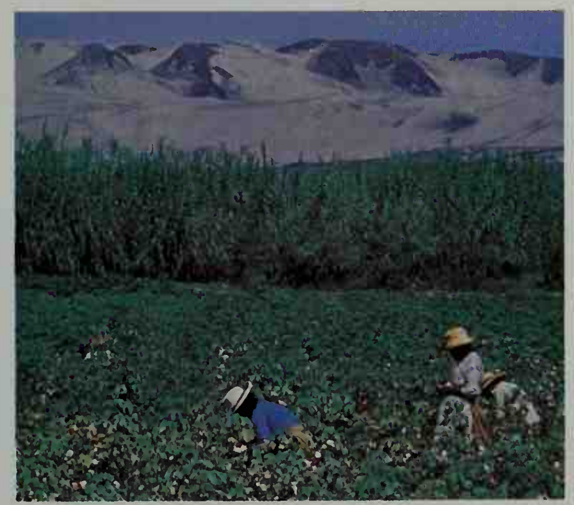
The first great Peruvian writer was Ricardo Palma, o wrote during the last half of the 1800's and the early 00's. Palma won fame throughout the world for his ries about life in colonial Peru. Later in the 1900's, ny talented Peruvian authors championed the cause the Indian. These writers include the political writer é Carlos Mariátegui, the poet César Vallejo, and the velists Ciro Alegría and José María Arguedas. During 1960's and 1970's, Mario Vargas Llosa became famous for his novels about the relations between Peru's social classes.

Land regions

Peru has three main land regions. They are, from west to east: (1) the coast, along the Pacific Ocean; (2) the highlands, the highest parts of the Peruvian Andes; and (3) the selva, a region of forests and jungles. Earthquakes occur frequently in Peru. Most of them center in the highlands, and their effects extend to the coast. A terrible earthquake in 1970 killed more than 66,000 people, chiefly in the northern highlands.

The coast consists of a long, narrow strip of land between the Pacific Ocean and the highlands. The region includes the western foothills of the Peruvian Andes. Most of Peru's large cities, commercial farms, and factories lie along the coast. Nearly all the coast is dry, rugged desert. But about 50 rivers, which flow from the mountains, cross the region. The rivers provide irrigation water for coastal farms as well as drinking water for the towns and cities.

The highlands consist of all areas of the Andes Mountains above 6,500 feet (1,980 meters). Narrow valleys and plateaus make up much of the region. The tallest highland peaks have snow the year around, and some have permanent glaciers. The highest peak is 22,205-foot (6,768-meter) Huascarán, an extinct volcano. Few trees grow in the highlands. But many of the valleys have a thick cover of grass. The Indians use these valleys for grazing herds of livestock, especially llamas and sheep. See **Andes Mountains**.



Lake Titicaca, in the southern highlands, is Peru's largest lake. Part of the lake lies in Bolivia. The Peruvian part covers 1,914 square miles (4,957 square kilometers). Lake Titicaca lies 12,507 feet (3,812 meters) above sea level. It is the highest navigable lake in the world. See **Lake Titicaca**.

The selva has two subregions—the high selva and the low selva. The *high selva* consists of the eastern foothills of the Andes. Unlike the dry western foothills,

the eastern foothills are covered with green forests. The *low selva* consists of low, flat plains east of the high selva. Thick rain forests and jungles cover almost all the low selva. The Amazon River, South America's longest river, flows through this region (see **Amazon River**).

Climate

Peru lies entirely within the tropics. But the Peru Current, an unusually cold ocean current, makes the coast cooler than is normal for a tropical region (see **Peru Current**). Coastal temperatures average 73 °F (23 °C) from November through April and 61 °F (16 °C) from May through October. Because of the high altitudes, temperatures in the highlands range even lower than do coastal temperatures. At the highest elevations, the temperature never rises above freezing. But at elevations below 10,000 feet (3,000 meters), frosts never occur. Most of the selva has high temperatures throughout the year. In many places, the temperature averages nearly 80 °F (27 °C).

The amount of rain, snow, and other forms of *precipitation* increases greatly from the coast to the selva. Because the air along the coast is cool, it cannot hold much moisture. In addition, air from the wet east loses its moisture in the Andes before it reaches the coast. As a result, the coast seldom receives more than 2 inches (5 centimeters) of rainfall a year. Much of the western highlands has less than 10 inches (25 centimeters) of annual precipitation.

The eastern highlands and the selva have a wet season from November through April and a dry season from May through October. Much of the eastern highlands receives more than 40 inches (100 centimeters) of precipitation a year. Most of the selva has at least 80 inches (200 centimeters) of precipitation annually, and some parts of the high selva receive more than twice that amount.

Economy

In the past, upper-class families controlled most of Peru's resources and industries. In 1968, a military government took power. The military leaders took over some businesses and gave part ownership of some farms and factories to the employees. In 1980, a civilian government began increasing private ownership. Government leaders hoped that increased private enterprise might relieve some of Peru's economic problems, including rapid inflation and high unemployment. At

st, the government was slow to carry out its policies. the 1990's, the government took a more aggressive proach to increasing private enterprise, and inflation is brought under control. But high unemployment and me other economic problems continued.

Agriculture. Farming is the chief occupation in Peru. any farm families own a small plot of land on which ey produce barely enough to feed themselves. Others ork on large *cooperative* farms. On such farms, the orkers own and operate the farm as a group.

Coffee, cotton, and sugar cane are Peru's chief export ops. Highland farms produce most of the coffee. Irrited farms along the coast grow most of the cotton d sugar cane. Most other crops are grown mainly to eet the country's own food needs. These crops include nanas, beans, corn, potatoes, and rice.

Mining. Peru ranks among the world's leading procers of copper, silver, and zinc. All these minerals are ned chiefly in the highlands. The country also proces much iron ore, lead, and petroleum. The richest n mines lie on the far south coast. The north coast d the selva have the largest petroleum deposits. The ghlands have important gold deposits.

About 40 small islands off the Peruvian coast have ge deposits of *guano* (bird droppings), which makes a od fertilizer. A government company mines the ano and sells it to mainland farmers. See **Guano.**

Fishing. Peru ranks among the leading counes. Each year, the country's fishing fleets take large antities of anchovies (sometimes called *anchovettas*), dines, tuna, and other ocean fishes. Sardines make by far the largest catch. Fish meal made from dried uvian sardines and anchovies is sold throughout the rld for use in livestock feed.

To avoid overfishing and ensure a profitable catch by uvian vessels, Peru claims authority over waters up 200 nautical miles (370 kilometers) off its coast. The vernment charges foreign vessels a high fee to fish in se waters and seizes vessels that refuse payment. s practice has caused a number of clashes between . fishing vessels and Peruvian authorities.

Manufacturing. Much manufacturing in Peru is done a small scale by individual craftworkers. But some nufacturing plants, chiefly along the coast, have many rkers and use mass-production methods. Many of se plants process raw materials for export. The chief cessed goods include fish meal, petroleum prods, refined metals, and sugar. Other large factories duce chemicals, furniture, paper products, proced foods, steel, and cotton and woolen textiles.

Trade. Peru's leading exports include fish meal, peeum, and minerals, especially copper and silver. The ntry also exports coffee, cotton, and sugar. Imports ude machinery, motor vehicles, other manufactured ds, dairy products, meat, and wheat.

he United States has long been Peru's chief trading tner. But since the 1950's, Peru has increased its trade outh America and with Europe and Japan.

Transportation. Travel across Peru is hindered by rugged Andes. Most of the country's roads are uned. Peru has an average of about 1 automobile for ry 50 people. The Peruvian section of the Pan Ameri Highway is the longest paved road. It extends 1,710 s (2,752 kilometers) along the coast (see **Pan American Highway**). A branch of the highway extends southeast from the coast into Bolivia. A number of side roads run east from the highway into the highlands, and some continue into the selva. But most travel in the selva is by river. Llamas often serve as pack animals in the highlands. Peru has two airlines. They connect Lima with all parts of Peru and with other Latin-American countries.

The Central Railway extends from the Greater Lima area to mines and ore refineries that are located high in the Andes. The railway climbs to 15,844 feet (4,829 meters) above sea level, higher than any other standard-gauge railroad in the world. The Southern Railway connects the Peruvian port of Mollendo with Arequipa and other cities and towns in the southern highlands. For additional information about transportation in Peru, see **Andes Mountains.**

Peru has few good natural harbors. But some harbors have been developed into important seaports. Callao ranks as the chief international port.

Communication. Lima has about seven daily newspapers, and most other cities have at least one. Most Peruvian newspapers are privately owned, and they represent a variety of political viewpoints.

Radio is an important means of mass communication in Peru. Most Peruvian families own a transistor radio. Programs are broadcast in both Spanish and Quechua. Peru has an average of about 1 television set for every 10 people. Many people watch television in public places. Television offers both local programs and foreign programs with Spanish sound tracks. The government operates some radio and television stations. Others are privately owned. The government owns and operates Peru's postal system.

History

Scholars believe that the first people to live in Peru were Indians who came from North America about 12,000 years ago (see **Indian, American** [Early days]). Gradually, the Indians learned to farm. They tamed the llama and began to cultivate the potato, which grew wild in the highlands. Potatoes became an important food in Peru long before they were known anywhere else in the world (see **Potato** [History]).

The Chavin Indians developed the first known civilization in Peru. The civilization reached its peak from about 800 to 400 B.C. Later, other groups, such as the Moche (or Mochica), Tiwanaku (Tiahuanaco), and Chimu, also developed civilizations in Peru. The Chimu built a large capital city called Chanchan. It was begun about A.D. 1000. Chanchan's ruins cover about 8 square miles (20 square kilometers) near present-day Trujillo.

About 1200, a people called the Inca founded a kingdom in southern Peru. The Inca were master architects and roadbuilders and accurate astronomers. They were also dedicated lawmakers and warriors. By the early 1500's, the Inca had built a great empire, and their civilization had reached its peak. The Inca rule extended north into parts of present-day Colombia and Ecuador and south as far as present-day Chile and Argentina. For detailed information, see **Inca**.

Spanish conquest and rule. In the mid-1520's, the Spanish adventurer Francisco Pizarro began to explore the west coast of South America. He had heard tales of the Inca empire and of its treasures of silver and gold.

About 1527, Pizarro and a few followers landed near t Inca city of Tumbes on Peru's north coast. They becam the first white men to set foot in Peru.

Pizarro saw enough riches at Tumbes to convince h that the legends about the Inca were true. He returnec in 1532 with about 180 men, who were later joined by other Spanish troops. By the end of 1533, the Spanish had easily conquered most of Peru, including the fabu lous city of Cusco, the Inca capital. In 1535, Pizarro founded Lima. It became the center of the Spanish go ernment in South America. For the story of the Spanis conquest of Peru, see **Inca** (History); **Pizarro, Francisc**

Spain ruled Peru for nearly 300 years. During this time, thousands of colonists arrived from Spain to see their fortune. Soon after the conquest, the king of Spa appointed a *viceroy* (governor) to enforce Spanish law and customs. The Indians had to become Christians a take Spanish names. Whole families were forced to work on plantations and in mines.

Peru quickly became one of Spain's most profitable colonies. But from time to time, Indians and *mestizos* (people of mixed Indian and Spanish ancestry) rebelle against the harsh white rule. A widespread revolt bro out in 1780. It was led by a mestizo who called himsel Tupac Amaru, after one of the last great Inca leaders. The Spaniards captured and executed him in 1781 an crushed the uprising the following year.

The war of independence. The chief heroes of Peru's independence from Spain were José de San Martín of Argentina and Simón Bolívar of Venezuela.

hey wanted to end European rule throughout South ımerica, and Peru became one of their main targets. Aost Peruvians took little or no part in the independ-nce movement. The white upper class benefited from panish rule, and the Indians expected to gain little if eru became independent.

San Martín invaded Peru in 1820 with an army of Ar-entines and Chileans. He declared the country inde-endent in 1821, though much of it remained under panish control. Bolívar led an army of Venezuelans and :olombians into Peru in 1823. The next year, Antonio osé de Sucre, one of Bolívar's generals, defeated a ırge Spanish force at Ayacucho in south-central Peru. he remaining Spanish troops held only the city of Ca-ao. They finally surrendered in 1826. Although Peru had ecome free, Spain did not formally recognize its inde-endence until 1879.

The early republic. Peru's first constitution went into ffect in 1827. It declared Peru a democratic republic. lso in 1827, the legislature elected General José de la lar as Peru's first president. He became the first in a ng series of military officers who held the presidency uring most of the 1800's. Many of the military presi-ents seized office in armed uprisings. The most impor-nt of these presidents was General Ramón Castilla.

Castilla became one of the first mestizos to hold high ublic office in Peru. He served as president from 1845 1851 and from 1855 to 1862. Castilla developed the uano industry and opened trade with Europe and the nited States. He also ended the *tribute* (tax) that Indian orkers had to pay their employers.

The War of the Pacific cost Peru its valuable nitrate eposits. Nitrates are minerals used in making fertilizer nd explosives. The War of the Pacific began as a quar-l between Bolivia and Chile over control of certain Bo-ian nitrate deposits. As a result of the dispute, Chile vaded Bolivia in 1879, marking the start of the war. eru entered the conflict because it had agreed to aid olivia in the event of war with Chile.

Chilean troops occupied Lima in 1881 and seized eru's nitrate-rich southern provinces of Tacna, Arica, nd Tarapacá. Chile also took Bolivia's coastal and desert nds around the city of Antofagasta. The Treaty of An-on ended the war in 1883. The treaty allowed Chile to keep the captured Peruvian provinces, but Chile returned Tacna to Peru in 1929.

The growth of U.S. influence. The War of the Pacific left Peru deeply in debt. Nicolás de Piérola, who had served as president during the war, took over again as president in 1895. He and most of the presidents who followed him in office encouraged foreign investment in Peru to help develop the country's resources and so reduce its debt. The U.S. firm of W. R. Grace and Company already had sizable investments in Peru, including a textile mill and a number of sugar plantations and refineries. In 1901 and 1902, a group of U.S. businessmen formed the Cerro de Pasco Corporation to develop Peru's copper deposits. The International Petroleum Company, a branch of the Standard Oil Company (New Jersey), now part of Exxon Mobil Corporation, gained control of the oil deposits in northwestern Peru in 1921.

Peru's economy improved in the early 1900's. But it worsened under the presidency of Augusto B. Leguía in the 1920's. Leguía, president from 1908 to 1912, was re-elected in 1919. He soon set himself up as a dictator. To finance his programs, Peru borrowed large sums of money from U.S. banks. Then early in 1930, Peru felt the first effects of the worldwide depression that began in 1929. The armed forces, alarmed by Peru's rising debt, overthrew Leguía and made Colonel Luis Sánchez Cerro president in August 1930.

The rise of APRA. Peru had a number of political parties before the 1920's. But most of them favored the upper class. In 1924, Víctor Raúl Haya de la Torre founded a party called APRA, an abbreviation for Alianza Popular Revolucionaria Americana (American Popular Revolutionary Alliance). APRA called for public ownership of Peru's basic industries and demanded equal rights for all citizens, including Indians.

Haya de la Torre ran for president against Sánchez Cerro in 1931 and lost. APRA charged dishonesty in vote counting and staged violent antigovernment protests. The government then jailed or killed hundreds of APRA supporters. It also banned the party from running political candidates. But APRA continued to gain followers during the 1930's and early 1940's.

In 1945, President Manuel Prado ordered the first election since 1931 in which APRA candidates could take part. But the party did not run a presidential candidate of its own. Instead, it supported José Luis Bustamante, a respected lawyer and diplomat, who won the election. But quarrels with other political groups led APRA to further acts of violence after the election, and Bustamante outlawed the party in 1948. Later that year, military leaders overthrew Bustamante's government and named General Manuel Odría as president. For eight years, Odría worked to reduce APRA's influence. But he legalized the party before the 1956 election, the first in which Peruvian women voted. Manuel Prado, who had been president from 1939 to 1945, gained APRA's support and won the election.

In the 1950's and early 1960's, APRA lost popularity, while the Popular Action Party led by Fernando Belaúnde Terry gained support. Belaúnde was elected president in 1963 and worked to improve the Indians' living conditions and educational opportunities.

Socialistic reforms. Peru began to have financial problems in the late 1960's. Many Peruvians blamed the

30 A civilian government, elected by the people, began working to increase private enterprise.

12 In April, President Alberto Fujimori suspended Peru's Constitution and dissolved the legislature.

13 Peru adopted a new constitution. It was written by a popularly elected Constituent Assembly.

problems on the United States, whose political and business interests in the country were increasing. In August 1968, President Belaúnde reached a complicated financial agreement with the International Petroleum Company in return for the company's Peruvian oil fields. Belaúnde's opponents charged that the agreement favored the company. In October, military leaders seized the government and formed a ruling *junta* (council). The junta named one of its members, General Juan Velasco Alvarado, as Peru's president.

The new government called itself the revolutionary government. It took over most of Peru's plantations and turned many of them into cooperatives. It also seized the holdings of International Petroleum, Cerro de Pasco, and W. R. Grace. In the early 1970's, the government began an industrial reform program that gave workers partial control over some industries.

By the mid-1970's, the government faced growing criticism. Members of the armed forces filled all major political posts, and civilians demanded a greater voice in the government.

Return to civilian government. In 1980, the people elected a civilian government to replace the junta. Belaúnde was again elected Peru's president. His government took some steps to increase private enterprise. Since the 1980's, leftist groups called Shining Path and the Tupac Amaru Revolutionary Movement have sought to overthrow the government by using guerrilla tactics.

In 1985, Alan García Pérez of APRA was elected president. In 1990, Alberto Fujimori, an independent, won th office. Both men increased private enterprise and took other steps aimed at improving the economy. But economic problems and violence continued.

Recent developments. In April 1992, Fujimori suspended Peru's Constitution and dissolved the legislature. He claimed there was corruption among government officials. He accused officials of failing to pass reforms to eliminate terrorism and the drug trade. Many Peruvians backed Fujimori. Others called him a dictator. In September, Peru's National Police arrested Abimael Guzmán Reynoso, the leader of Shining Path. In October, he and 10 others were convicted of high treason fo terrorist crimes and sentenced to life in prison.

In November 1992, popular elections were held to form a Constituent Assembly. Supporters of Fujimori won a majority of the seats. The Assembly wrote a new constitution that took effect in December 1993. Fujimori and the Assembly continued to serve until new presidential and legislative elections were held in 1995. In th elections, Fujimori was reelected president, and his par ty won a majority of the seats in the Congress.

In December 1996, Tupac Amaru rebels seized the Japanese ambassador's residence in Lima and took a group, mainly diplomats and business executives, as hostages. In April 1997, Peruvian troops rescued the 72 hostages still held. All the rebels were killed in the raid.

In May 2000, Fujimori was reelected to a third term a president. Opponents accused him of vote fraud, and many opposition supporters boycotted the election or spoiled their ballots. Later that year, a bribery scandal ir volving a top Fujimori aide led to Fujimori's resignation as Peru's president. But the Peruvian National Assembly refused to accept his resignation and instead declared him "morally unfit" for the presidency and removed hin from office. In June 2001, Alejandro Toledo was electec president of Peru. Toledo had run against Fujimori in th previous year's election. David J. Robinson

Pest control is a term that identifies various methods used to reduce or eliminate pests. Any living thing that kills plants or stunts their growth, carries disease, or is harmful in other ways may be considered a pest. Pests include insects, weeds, mammals, *pathogens* (disease-causing microorganisms), and *nematodes* (microscopic roundworms). The two major pest control methods are (1) *pesticides,* chemicals used to kill pests, and (2) natural pest control, which uses various preventive measures instead of chemicals. Many pest control experts favor a diverse approach called *integrated pest management,*

which combines pesticides and natural control methods.

Pesticides are classified according to the pests they control. The four main types of pesticides are (1) herbicides, (2) fungicides, (3) rodenticides, and (4) insecticides.

Herbicides eliminate plants that grow where they are not wanted. Farmers use them to reduce weeds among their crops. Herbicides also control weeds in such public areas as parks and ponds. People use herbicides in their yards to get rid of crab grass, dandelions, and other weeds

Fungicides. Certain fungi cause disease and may infect both plants and animals, including human beings. Fungicides control plant diseases that infect food crops. Wood used for building houses is often treated with fungicides to prevent dry rot.

Rodenticides are used to control rats and other rodents that destroy stored food. Rats also carry bacteria that cause such diseases as rabies and typhus.

Insecticides. Farmers use insecticides to protect their crops from insect damage. In urban areas, public health officials use them to fight mosquitoes and other insects that carry germs. People use insecticides indoors to control such pests as ants and cockroaches.

Effects of pesticide use. Pests may develop resistance to pesticides so that higher dosages must be used over time. Eventually pesticides can become ineffective, so there is a constant need to create new pesticides. Over 600 species of plant and animal pests have been found to be resistant to at least one type of pesticide.

Pesticides are poisons that can have unintended effects on people and on the environment. Wind or rain can carry herbicides from weeds to desirable plant species, such as trees and flowers. Insecticides kill beneficial insects, such as honey bees and ladybugs. Health officials worry about small amounts of pesticides that remain on food. Most people and many animals have pesticide traces in their fat tissue.

People used chemical pesticides for many years without realizing their harmful effects on humans and the environment. In 1962, American marine biologist Rachel Carson wrote the book *Silent Spring* to call public attention to pesticide dangers. The book helped to reduce pesticide use throughout the world.

In the United States, the Federal Insecticide, Fungicide, and Rodenticide Act, originally enacted in 1947, limits pesticide use on food. It requires users of the most dangerous pesticides—called *restricted use pesticides*—to have a special license to use them. The federal government may order people who use pesticides improperly to pay large fines.

Natural pest control helps avoid pest attacks without the use of chemical pesticides. For example, destroying plants after harvest will deny pests food and shelter. *Crop rotation* (planting a different crop each year) prevents excess numbers of any one pest from building up. Pest managers also use biological control methods, such as encouraging a pest's natural enemies.

Integrated pest management, also known as IPM, has largely replaced reliance on pesticides as an approach to pest control. IPM combines a limited use of chemical pesticides with natural control methods. Pest managers track levels of pest infestation and apply pesticides only when they will produce the greatest benefits. For example, if a pest left untreated would produce $5 worth of damage and applying a pesticide would cost $100, then the best decision is to leave the pest untreat ed. Pest managers use natural control measures until t cost of not controlling a pest exceeds the cost of apply ing a pesticide. H. Michael Linker

Pestalozzi, *pehs tuh LAHT see,* **Johann Heinrich** (1746-1827), was a Swiss educator who became a pioneer of modern education. Many of his ideas were ne and startling for his time but have been absorbed into present-day educational practices and theory.

Pestalozzi was one of the first educators to base his ideas on child psychology. He adjusted his teaching methods to children's stages of development. In all his theories, he stressed the dignity and worth of each pe son. He believed the purpose of education is to ensur the full development of each student's unique abilities He thought education should aim for the intellectual, physical, and moral development of the individual.

Pestalozzi's teaching methods were revolutionary fo his time. For example, he felt children could learn best in an atmosphere of love and freedom rather than by harsh discipline. Therefore, a child's education should begin in a warm and loving family. He also taught children to use their senses and to learn from doing rathe than simply memorizing facts.

Many of Pestalozzi's educational theories were base on what he called *Anschauung,* a German word that means *perception* or *observation.* He felt that observation of objects, other people, and moral situations is t basis of all true knowledge. He believed children progress from an understanding of simple objects to a comprehension of difficult philosophical concepts.

Pestalozzi left a lasting impact on education. His em phasis on the importance of understanding children helped establish the need for careful teacher training.

Pestalozzi was born Jan. 12, 1746, in Zurich, Switzerland. He attended the University of Zurich, where he f studied for the ministry and later changed to law. He abandoned both careers and took up farming. In 1774 he turned his farm into a school for poor children, where he developed many of his educational ideas. In 1798, the Swiss government appointed Pestalozzi to head an orphanage at Stans, near Lucerne. During the early 1800's, Pestalozzi founded schools in Burgdorf a Yverdon. His work at these schools brought him inter tional recognition. Educators from Europe and North America came to study his methods. Many of them formed teacher institutes based on Pestalozzi's ideas. major theories are presented in his books *Leonard an Gertrude* (1781-1787) and *How Gertrude Teaches Her Children* (1801). A pet depends on its owner for food, shelter, and grooming. Many children learn responsibility by caring for pets. In this photograph, a girl and her father bathe their Irish setter.

'et. Animals have been kept as pets by people in all arts of the world for thousands of years. The most ommon pets are dogs, cats, parakeets, canaries, and sh. But many people keep unusual pets, such as rac-oons, skunks, alligators, and monkeys. Many Japanese hildren tame mice and teach them to dance to music. xplorers in Antarctica have treated penguins as pets. he people of India make pets of mongooses. Cormo-ants are common pets in China.

Pets can make interesting, playful companions. Peo-le enjoy teaching them to do tricks and to obey com-nands. Pet owners often consider their pet to be a nember of the family. Many children spend more time ith their pets than they do with adults. By caring for ets, children learn responsibility. They must see that ieir pets have food, exercise, and a proper place to live. lost children like talking to and even telling secrets to ieir pets.

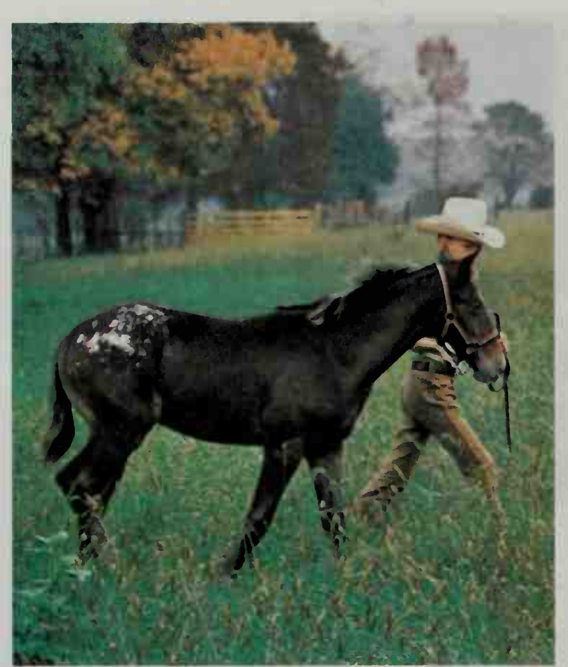
Pets also can contribute to a person's general well-eing. Research shows that being with animals can im-rove a person's morale, and that the presence of pets an lower one's blood pressure. Many people look and el more relaxed while with their pet. Many people liv-g alone in nursing homes or in hospitals enjoy com-unity programs that bring pets to visit. Today, many ich institutions keep cats, birds, fish, and other pets for eir residents.

In addition to providing companionship, many pets so serve other useful purposes. Dogs hunt, guard roperty, herd cattle and sheep, and assist blind people. ats often keep homes and barns free from mice and ts. Pets such as frogs and toads help keep gardens ee from certain kinds of insects. Canaries fill the air ith happy, pleasing songs.

Kinds of pets

Pets for the home. The kind of home you live in, and here you live have much to do with the kind of pet you ioose. Dogs, cats, birds, and fish are easy to care for in most any kind of home.

Before choosing a dog as a pet, you should consider e size of both your home and the dog. For example, a llie needs a large home with a big yard for exercise. If you live in an apartment, you should be sure pets are al-lowed. Then choose a small dog, such as a cocker span-iel. A small dog can get most of its exercise by playing around the house, and needs only short walks outside for fresh air.



Cats do not depend on their owners as much as dogs do. Many people prefer them for this reason. They are quieter and gentler than dogs. But they, too, need out-door exercise. On pleasant days, a cat can run around in a yard. A cat should always be brought inside at night.

Various kinds of birds make fine pets for a small home or apartment. They live in cages that take little

space, and their singing, beauty, and antics will please you by the hour. Canaries sing songs, and their peppy, cheerful ways make them pleasing pets. The parakeet is one of the most popular birds. It can learn to talk and is a great clown. A parakeet can be trained to walk a tightrope, go through a tunnel, push and pull toys, and ride in toy cars or trains.

Fish have one advantage over most other pets. They can be left alone for a day or two without food. Most fish need food only a few times a week. You can make what is often called a *balanced aquarium* by growing plants in the fish tank. Plants supply some oxygen for the fish. The water need not be changed, but sometimes more water must be added to replace that which evaporates. Some kinds of tropical fish need extra care, such as controlled temperature, special foods, or oxygen bubbled through the water (see **Aquarium, Home**).

Other small animals, including white mice, guinea pigs, and hamsters, may be kept as pets in a home.

Farm pets. Farm children usually have many kinds of pets. Almost every farm has one or more dogs, and cats to keep down the mice. The children also play with and care for the baby animals that live on the farm. They may make pets of lambs, rabbits, and even pigs. Baby chickens and ducklings often follow children around the yard, hoping for food. The children may have a pony or a gentle horse to ride. Many farm boys and girls raise calves to show at county fairs. They brush their calves to keep them clean and sleek. They also make sure that the animals have clean straw for their beds.

Pets in school. Many school classes keep animals in the classroom as pets. Boys and girls learn how these animals eat, sleep, play, and take care of their young. They build houses or cages for their pets, and feed and care for them. Rabbits, guinea pigs, hamsters, mice, rats, fish, frogs, toads, and snakes are among the favorite schoolroom pets. Sometimes classes build glass ant houses or beehives. Then they can watch the activities of a whole group of insects.

Choosing a pet

Before buying a pet, learn as much as possible about all kinds of pets. Choose an animal that can live comfortably in the amount of space you have for it. Find out whether the pet needs outdoor exercise and, if so, how often. Will the pet need care during the day and will someone be at home to take care of it? How does the animal behave? Does it act differently with strangers? Is it playful with young children, or does it become irritable? What foods does it eat, and how much do these foods cost?

The only way to be certain what a pet will look like when it grows up, and how it will behave as an adult, is to buy a *purebred* animal. This is an animal whose parents were both of the same breed. But *mongrels,* or animals of mixed breeds, also make fine pets. Buy your pet from someone who has raised that kind of animal for a long time, or from a well-kept pet shop. Then you will know the animal has had good care, proper food, and all necessary vaccinations against disease.

Training your pet

Before you start to train any kind of pet, you must have its respect and affection. You must always treat

Jim Collins

: fairly. For example, the first time your dog jumps up at ou, make it get down. If you let your dog jump on you vhen its paws are dry and clean, it probably will do so vhen they are wet and dirty. The dog does not know vhen it should not jump on you, and so you should not ɜt it form the habit. Say firmly, "No, no" or, "Get down" s you put your pet down. Do this every time, until the og learns not to jump on you.

Always speak gently to your pet, and try not to make uick, unfamiliar movements. This does not mean you annot scold your pet. If the animal misbehaves, scold it t once. Use simple words, such as *no, no* or *naughty,* nd say them so that the pet knows you are unhappy vith it. Do not shout or speak angrily. The pet will not ɜmember for long why it is being scolded, so make the colding short. Of course, this kind of training is useless or such pets as fish and turtles.

House training. You should make preparations for ouse training a puppy or kitten even before bringing it ome. For example, you can make a den-bed for a uppy by building a stout box with a lid and air holes. he puppy will be discouraged from using the box as a oilet if you make it only large enough for the pet to lie own and gnaw a bone. A dog instinctively wants to ɜep its bed clean. The animal cannot get out of the box y itself, and so it will make noise to let you know its ɜed.

Bring the puppy home in the morning, so it can take ɜveral naps in the box that day. Meanwhile, select a ace outdoors that you want your pet to use as a toilet. fter you clean up the puppy's first body wastes, take em to the outdoor place and bring the animal there. ne smell of its wastes will let the puppy know where to lieve itself. When your puppy uses the right place, aise the pet and take it back into the house. The puppy ould spend the night in the box and should not be ven food or water after 6 p.m.

A puppy needs to be taken out several times a day: (1) hen it awakens in the morning, (2) after naps, (3) after eding, and (4) before play. Any kind of excitement akes a puppy want to relieve itself.

A puppy should not be housebroken indoors on per. You might not be able to retrain it to relieve itself an outdoor spot. You should not let the puppy get you in the middle of the night. Nor should you allow rain snow to stop you from taking your pet out. Always ke the puppy to its spot during the housebreaking peod. Do not just put it outside and let it find its own way. ter about three days, the puppy will probably not ake any mistakes.

To train a kitten, buy a cat tray and *litter* (artificial nd) at a pet store. Or you can use a box with clean nd. Place the tray near the kitten's food dish, and put e animal into the tray a number of times. A cat instincely buries its body wastes, and so it will use the tray mediately. You should sift the wastes from the litter ily and change the litter weekly.

Tricks. To teach an animal a trick, you must first ke it understand what you want it to do. To teach a g to sit, for example, push it down to a sitting posin. As you do this, say the word *sit.* Praise your pet ien it sits correctly. Soon you will find that whenever u say, "Sit," the dog will sit. To make it sit up, raise its nt feet as you say, "Sit up." A dog can learn many

commands, and such tricks as to fetch, to roll over, to beg, to "say prayers," and to "play dead."

Dogs tire quickly as you train them. You should not work with them more than 15 minutes at a time, and perhaps only once or twice a day. Stop at once if the dog is not paying attention, or if something else seems more interesting to it. You must have the dog's attention, and it must complete each command. Never allow your pet to perform a trick only halfway. And never become impatient when you try to teach it tricks.

Reward a dog with a pat on the head and a few words of praise when it has performed its lesson correctly. If you want to give the animal a special treat, feed it a dog biscuit or a piece of dog candy to exercise its teeth and gums. Ordinary cake, cookies, and candy are bad for a dog and should never be given to the pet.

A cat can be taught to do simple tricks, such as jumping in the air for a ball, leaping over a stick, or walking on its hind legs. You must be patient and gentle to interest the cat in the trick and gain its confidence. Cats should be rewarded with a piece of meat when they perform well. Parakeets usually learn tricks themselves when you put a ladder or toy car in their cages. Fish can learn to come to the side of the tank to receive their food, if you tap gently on the tank each time you feed them.

For work. Most kinds of dogs can be trained to do certain types of work. Dogs can retrieve, or bring back, game for hunters. They can help herd livestock, pull carts or sleds, and perform many other tasks. Careful training will bring the dog to perfect responses. For example, start training retrievers when they are about six months old. To teach a puppy to return an object you have thrown, give a command such as *fetch* as you throw the object. As the dog learns to return the object, throw it farther and farther away. Training in retrieving from the water starts by throwing an object a short dis-

tance into the water. Increase the distance until the dog retrieves the object perfectly.

Taking care of pets

Feeding. The first rule for feeding any pet is to keep its dishes clean. Wash them thoroughly every day. Never overfeed your pet. The animal should always have enough exercise and look sleek and slim. Give a dog only as much food as it will eat without leaving any food in the dish. If it leaves the dish before emptying it, take it away. Feed your pet less the next time. Feeding a dog the right food at regular times helps protect it against sickness.

A balanced diet is necessary if your pet is to be healthy. You can buy prepared food for most kinds of pets. Scientists plan these foods so that they contain the right amounts of vitamins, minerals, and proteins for each type of animal. By using these foods, you can be sure that your pet receives the right nourishment. Prepared foods usually do not need anything added to them. But you may want to give your pet a treat, such as a little horse meat for the dog or cat, or a piece of apple or some greens for the parakeet. Feed your pet at regular times, and be sure that it always has plenty of fresh water.

Housing. All pets must have good houses. Birds should live in cages suitable for their size and activity. For smaller birds, the cage bars should be close enough together so that the bird cannot push its head between the bars and strangle itself. The perches should be $\frac{1}{2}$ inch (1.3 centimeters) in diameter for canaries and parakeets, and 1 inch (2.5 centimeters) in diameter for mynas. Canaries, parakeets, and other flying birds should have room to fly inside the cage. Put their perches at the ends of the cage. Hopping birds, such as finches and mynas, should have the perches nearer to the bottom of the cage and closer together.

A dog or cat should have a warm, dry place for its bed. A basket, box, or pet bed will keep the pet off the floor and protect it from drafts. A dog living outdoors must have a house that is free from drafts. The door of the house should face away from the wind, and it should be covered or sheltered against rain and snow. The house should be just large enough for the animal to stand up and turn around. A house that is too large will be cold.

Cleanliness. Most pets keep themselves clean. Cats sit for hours washing themselves. Birds preen themselves, or clean their feathers with their beaks. Canaries and mynas enjoy hopping in water and splashing around. Parakeets like to roll on wet lettuce leaves or to be sprayed with water from an atomizer.

Dogs and cats should not be bathed too often. Bathing removes the natural oils from their hair and skin. This makes them itch and scratch, and soon they may have open sores. They usually need baths only when they become very dirty. If your dog or cat becomes muddy, wipe off the loose mud, let its coat dry, then brush its coat well.

Treating illness. Most pets will enjoy good health with proper food, housing, and grooming. If one should be hurt, swallow something harmful, or otherwise become ill, it should be taken to a *veterinarian,* or animal doctor.

Don't try to treat your pet's illness yourself, unless you know exactly what is wrong and what to do to remedy the illness. Home treatment may seriously delay finding out what is wrong with your pet, and may even harm the animal.

Preventing illness. Most pet illnesses can be prevented. A veterinarian can vaccinate a puppy to protect it from such fatal diseases as distemper, infectious canine hepatitis, leptospirosis, and rabies. A kitten may be vaccinated against cat distemper and feline leukemia, both deadly cat diseases. Vaccination should begin when the pet is taken from its mother's milk and should continue throughout its life.

A sick animal can infect other animals. By keeping your pet at home, you can lessen its chances of getting sick. A puppy should be kept in the home and yard. If you take it elsewhere, you should keep it on a leash and avoid areas where other dogs—or rats—may be found. An infected dog or rat can spread leptospirosis through its urine.

Tiny parasites, such as fleas, mites, and ticks, may transmit disease germs from a sick animal to a healthy one. Pet stores sell flea collars, powders, and soaps that can rid your pet of these pests.

Birth control. Every year, animal shelters destroy millions of unwanted cats and dogs. Therefore, you should not allow your pet to have babies unless you can be sure they will have a good home.

Veterinarians can prevent an animal from having or fathering babies by *neutering* it—that is, by removing some of its sex organs. This operation is called *spaying* when performed on a female and *castration* when done on a male.

Neutering a pet may also eliminate some kinds of undesirable behavior. For example, castrating a cat before it has had sexual experience can prevent it from chasing females and fighting. Dogs and cats should be neutered at the time the veterinarian considers best for the health and size of the animal. Contrary to popular belief, it is not necessary for the pet to experience its first period of *heat* (sexual excitement) before being neutered. 'étain, *PAY TAN,* **Henri Philippe,** *ahn REE fee LEEP* 856-1951), became a national hero of France because f his military leadership in World War I. Yet he was ied and imprisoned for treason in his old age because f his collaboration with the Germans in World War II.

Military hero. Pétain was born at Cauchy-la-Tour. He vas educated at the French military academy of Saint 'yr and served as an army officer. In 1916, during World Var I, he commanded the French forces in the heroic lefense of Verdun (see **Verdun, Battles of**). Here he poke his famous words "They shall not pass." In April 917, Pétain was made chief of staff. He served as comnander in chief on the Western Front from May 1917 to Aarch 1918. Pétain was nade a Marshal of France n 1918.

Political career. Pétain erved briefly as minister f war in 1934. His critics ccused him of secret hosility to the French Republic and also of sympathy for he dictatorial government of Francisco Franco in pain. He served as ambasador to Spain in 1939 and 940. Pétain was called ome to be vice premier of rance in the desperate Vorld War II days of May 1940, when France was unble to stop the German invasion. On June 16, 1940, at he age of 84, Pétain became premier. Against the objecions of some of his colleagues, he arranged the armistice with Germany.

Collaborator. Pétain became "chief of state" in the rench government when its capital moved to Vichy. He ccepted collaboration with the Germans as an inescapble necessity. But he also saw it as an opportunity to rehape France along authoritarian lines. His government ndertook measures against Jews, paid heavy financial ribute to the Germans, and sent many French workers o Germany. Pétain's chief supporters included veterans vho had served under him in World War I.

The Germans overran all of France in 1942. But Pétain, hough essentially powerless, insisted on maintaining a alse appearance of French sovereignty. After the Allied roops landed in France in June 1944, the Germans took im to Baden, where he remained until after the war. In 945, Pétain was returned to France. He was tried for reason and was convicted. Pétain died in prison at the ge of 95. John F. Sweets

Peter I (1844-1921), a Serbian king, ruled from 1903 to 921. After the death of his father, Prince Alexander, Peter became head of the Karageorgevic dynasty. He became king when the king of Serbia, also named Alexander, was assassinated. Upon assuming the throne, Peter ought help from Russia in acquiring the province of Bosnia. This province, ruled by Austria, was the home of many Slavs. Russia's support of Peter, together with the assassination of Archduke Francis Ferdinand of Austria by Serbs, helped produce World War I. After the war, Serbia and Bosnia became part of the Kingdom of the Serbs, Croats, and Slovenes (later renamed Yugoslavia). Peter retired from the throne in 1914, and his son Alexander served as regent.

Peter was born in Belgrade. As a boy, he and his family lived in exile, and Peter was educated in Hungary and France. R. V. Burks

Peter I, the Great (1672-1725), was one of the most famous rulers in history. He ruled first as *czar* (king) of Russia and later became Russia's first emperor. Peter transformed Russia from an isolated and backward country into a great European power.

Early life. Peter was born in Moscow. His father was Czar Alexis. Alexis died in 1676 and was succeeded as czar by his oldest son, Feodor. Feodor died in 1682. Peter then came to the throne at the age of 10, along with his weak-minded half brother Ivan V. However, Peter's half sister Sophia actually ruled Russia until 1689. Peter's followers forced Sophia to retire that year, and Peter eventually became the sole ruler of Russia.

Peter had been interested in military matters as a youth. He also had enjoyed spending time with foreign military officers who lived in Moscow, and he learned much about European civilization from them. In 1695, a number of these officers helped Peter lead a force against the Ottoman Empire. Peter conquered the Ottoman port of Azov on the Black Sea in 1696.

In 1697 and 1698, Peter toured Western Europe with a group of Russian delegates to seek allies for Russia against the Ottoman Empire. He traveled for about 17 months, mostly in England and the Netherlands. Peter also recruited Western experts to bring modern techniques of engineering, architecture, art, and science to Russia. Russia then lagged far behind other European nations in these areas.

A revolt of his royal guards forced Peter to return to Russia in 1698. Peter crushed the revolt. This victory

Peter the Great was a powerful ruler who succeeded in bringing Western European culture and customs to Russia.

made him the unquestioned master of Russia.

Foreign policy. From 1700 to 1721, Peter led Russia in a war against Sweden. When the war began, Sweden was the leading power in northern Europe. With the help of his Western advisers, Peter improved Russia's army, created a navy, and made his government more efficient in raising troops and money for his war effort. By the end of the war, Russia had gained control over important territory along the eastern shores of the Baltic Sea. This land gave Russia a direct approach by water to the rest of Europe.

In 1712, the Ottomans forced Peter to turn over the port of Azov and other territories taken earlier from them. But in 1722 and 1723, Peter attacked Persia and conquered territory along the Caspian Sea. Peter's foreign conquests helped Russia greatly to expand its trade with other countries. Peter's conquests also enormously increased Russia's political importance in Europe.

Policies within Russia. One of Peter's chief goals was to end the inefficiency and corruption in Russia's government. Peter strengthened his power as czar and created a senate to supervise the Russian government. He began a policy of appointing people to high military or administrative offices according to merit and seniority. Previously, these appointments were based on family background. Peter also abolished the independence of the Russian Orthodox Church.

Peter's programs led to the expansion of industry and foreign trade and the construction of new roads and canals. He also laid the basis for the Russian Academy of Sciences, started Russia's first newspaper, and founded technical schools, a museum, a public library, and an art gallery. Because of his admiration for European society, Peter forced Russia's nobility to adopt many Western customs.

In 1703, Peter founded the city of St. Petersburg on territory taken from Sweden. He modeled it after cities in Western Europe. Peter made St. Petersburg the capital of Russia and used it as the focus of his efforts to "Westernize" Russian life.

Peter's rule also had some harmful effects. To finance his military campaigns and domestic reforms, Peter imposed high taxes on the Russian people. He also dealt harshly with people who opposed the reforms. Peter forced many Russians to work against their will in his mines and factories and on building projects. Peter also extended serfdom, a system under which the majority of Russian peasants lived in conditions little better than slavery (see **Serf**). James Cracraft

Peter, Epistles of, are the 21st and 22nd books of the New Testament. They are letters from the apostle Peter. Most scholars doubt that Peter actually wrote the letters. They believe the letters were written in his name by someone else. The first Epistle was probably written between A.D. 81 and 96 or 98 and 117, during a persecution of the church by the Roman Empire. The letter's main purpose is to encourage perseverance in Christian faith despite suffering. The second Epistle may have been written as late as A.D. 130 or 140. It is probably the last book of the New Testament to be composed. Its main purpose is to argue that Jesus Christ will some day return, despite doubts that had arisen concerning His Second Coming. Terrance D. Callan

Peter, Saint (?-A.D. 64?), was a leading apostle of Jesus Christ. He was a leader of the early Christian community in Jerusalem and is a prominent figure in the New Testament. Peter's original name was Simon. Jesus gave him the name Peter, which means *rock* in Greek. Peter is sometimes called Simon Peter in the New Testament.

In a passage from the New Testament, Jesus is portrayed as saying to Peter:

"And I say unto thee, That thou art Peter, and upon this rock I will build my church; and the gates of hell shall not prevail against it. And I will give unto thee the keys of the kingdom of heaven: and whatsoever thou shalt bind on earth shall be bound in heaven: and whatsoever thou shalt loose on earth shall be loosed in heaven." (Matt. 16:18-19).

Traditionally, Roman Catholics regard the above passage as evidence that Jesus chose Peter to be the first head of His church. They believe He established the position of pope through Peter. Protestant scholars interpret the passage to mean that Jesus meant His church to be founded on Peter's faith in Him. But both groups agree that Peter led the early Christian community.

Early life. Peter, a Jew by birth, was born in Bethsaida, a town in Palestine on the east bank of the Jordan River. The apostle Andrew was his brother, and the apostle Philip also came from Bethsaida. Peter later moved to the nearby town of Capernaum on the bank of the Sea of Galilee, where he became a fisherman. The New Testament portrays him as warm, generous, stubborn, and impulsive. He was married and may have had children.

Peter and Andrew met Jesus while they were fishermen. Jesus said to the brothers, "Follow me, and I will make you fishers of men" (Mark 1:17). Peter and Andrew left their homes and joined Jesus on His travels.

Life as an apostle. Stories in the New Testament reflect Peter's importance in the Christian community as a close friend of Jesus and His followers. Peter, along with the apostles James and John, is said to have witnessed the Transfiguration (see **Transfiguration**). Jesus also talked with Peter about religious matters. When Jesus asked the apostles about His identity, Peter replied, "Thou art the Christ" (Mark 8:29).

The Gospels suggest that Peter understood Jesus and His significance only after the Resurrection. Before the Crucifixion, Peter denied three times that he knew Jesus. Peter later wept in repentance (Mark 14:72). Peter was one of the first witnesses of the Resurrection listed

by Saint Paul (I Corinthians 15:5). After the Resurrection, Jesus appeared to Peter in a vision. This vision and the faith in Jesus that it produced is the foundation of Christianity. After the Resurrection, Peter became an authority among the Jewish Christians in Jerusalem. He probably served as a peacemaker between conservative Aramaic-speaking Jews led by James and the more liberal Greek-speaking Jews led by Paul. Peter is sometimes called the "Apostle to the Jews."

Later years. Peter apparently left Jerusalem with his wife and became a wandering missionary. According to Christian tradition, Peter became the first bishop of Antioch in Syria, and the first bishop of Rome. He may have died a martyr in Rome during the persecution of Christians by the Emperor Nero from A.D. 64 to 68. According to Christian tradition, Peter was buried under what is now St. Peter's Basilica in Vatican City. There is no conclusive evidence for any event related to his death.

No undisputed writings by Peter have been preserved. Writings by Paul describe Peter as a source of oral stories about Jesus. The New Testament includes two essays called *Epistles of Peter.* The First Epistle, which urges a group of Christian converts to remain faithful in times of persecution, may have been written by Peter. However, the Second Epistle was written by an unknown author sometime during the 100's.

Monuments to Peter, in addition to stories about him, honor him as a missionary and an organizer of the Christian church. By the 100's, a shrine that many believed contained Peter's remains had been built in Rome. The shrine attracted many Christian pilgrims. St. Peter's Basilica stands on the site today. Early Christians honored Peter in art and literature, where he was called the Fisherman, the Rock, and the Shepherd.

By about 450, many Christians believed that the pope was the successor of Peter. They also believed Peter was a saint. June 29 is the feast day of Saint Peter.

Peter Pan is the boy hero in several fantasies written by the Scottish author J. M. Barrie. The character first appeared in Barrie's novel *The Little White Bird* (1902). Barrie adapted part of the novel into the play *Peter Pan* (1904). Several chapters of the novel were published in 1906 as *Peter Pan in Kensington Gardens.* Barrie also wrote the novel *Peter Pan and Wendy* (1911).

The play *Peter Pan* provides the best-known version of the boy's adventures. In the play, Peter Pan has run away to Never-Never Land to escape growing up. One night, he returns to the human world and meets the three Darling children—Wendy, John, and Michael. Peter persuades them to fly with him and the fairy Tinker Bell back to Never-Never Land. There the Darlings and Peter have many adventures. Other characters include a crocodile, the Indian princess Tiger Lily, and the evil pirate Captain Hook. James Douglas Merritt

Peter the Hermit (1050?-1115?) was a monk of Amiens who is famous as a preacher of the First Crusade. Little is known of his life from the time of his birth in Amiens until 1095. At that time he began to preach the necessity of a crusade to get back the Holy Land, which was in Muslim hands. He rode about France on muleback, dressed in a monk's cloak of rough cloth and bearing a crucifix. He hoped to inspire people to join him.

In 1096, Peter set out for Palestine with many undisciplined followers, mostly from the poorer classes. After struggling through Europe and into Asia Minor, most followers were massacred by the Turks. Peter and the survivors joined Godfrey of Bouillon's army and helped capture Jerusalem. William J. Petersburg (pop. 33,740), in southeastern Virginia, is one of the most historic cities of the South. It lies on the Appomattox River, about 20 miles south of Richmond, Virginia's capital (see **Virginia** [political map]). Petersburg and Richmond and their suburbs form a metropolitan area of 996,512 people.

In 1676, Petersburg's citizens were active in Bacon's Rebellion, a revolt against the English government. The city was attacked and burned in 1781 by British expeditions led by the American traitor Benedict Arnold. During the War of 1812, Petersburg became known as *cockade city* because of the jaunty feathered hats worn by its soldiers. The city was the "last ditch of the Confederacy" during the American Civil War (1861-1865). When Petersburg fell in 1865, the Southern forces evacuated Richmond. General Robert E. Lee, head of the Confederate Army, surrendered soon afterward, ending the war.

The first settlement in Petersburg was made in 1646 near a falls on the Appomattox River. The falls provided a source of power for industrial development, and Petersburg became a major manufacturing center. In the late 1800's, the city was especially known for its tobacco products. Today, Petersburg's chief industries are health care, tourism, and the manufacture of computer software, forest products, optical lenses and frames, roller bearings, and trunks and other storage containers. Virginia State University is in the city. Petersburg has a council-manager government. Susan L. Woodward

Peterson, Oscar (1925-), is one of the great pianists in the history of jazz. He is known for his brilliant technique and his creative extended solos. He is also a composer and created the expansive composition *Canadiana Suite* (1964).

Peterson was born in Montreal, Canada. He was trained in classical piano from the age of 6. In 1949, Peterson appeared in a "Jazz at the Philharmonic" concert at Carnegie Hall. He quickly achieved fame worldwide. From 1951 to 1966, the Oscar Peterson Trio featured Peterson on piano, Ray Brown on bass, and a third musician on guitar or drums. Most notable were Barney Kessel, Herb Ellis, and Joe Pass on guitar and Ed Thigpen on drums. Peterson has worked with many leading jazz musicians and has performed as guest soloist with several symphony orchestras. Frank Tirro

Peterson, Roger Tory (1908-1996), was an American artist, naturalist, and author. His popular paintings and

illustrations of birds for books led to the development of a series of nature handbooks called the *Peterson Field Guide Series.* His work has helped people identify and appreciate animals in their natural environment and has highlighted the value of wildlife conservation.

Peterson first collected his illustrations and methods of identifying birds in a book called *Field Guide to the Birds* (1934). Later, he created *A Field Guide to Western Birds* (1941). In 1946, he became editor of the *Peterson Field Guide Series.* Peterson expanded the series to include guides on birds of Europe and Mexico, on other animals, on plants, and on minerals.

Peterson was born in Jamestown, New York. His books include *Birds Over America* (1948), *The Birds* (1963), and *Penguins* (1979). With James Fisher, a naturalist, Peterson wrote *Wild America* (1955) and *The World of Birds* (1964). In 1986, Peterson and several colleagues founded the Roger Tory Peterson Institute of Natural History in Jamestown. G. J. Kenagy

Petipa, *peh tee PAH,* **Marius,** *ma RYOOS* (1818-1910), was a great French *choreographer* (creator of dances). Petipa joined the ballet of the Imperial Theatre in St. Petersburg, Russia, in 1847. He was its head from 1862 to 1903. He composed 57 evening-long ballets and many shorter ones. The best known include *Sleeping Beauty, Raymonda, La Bayadère,* and Act III of *Swan Lake.*

Petipa's style is clear and grand. It demands highly trained dancers with a dramatic yet cool and aristocratic quality. Petipa made the St. Petersburg ballet the finest in the world. Its school produced such great dancers as Vaslav Nijinsky, Anna Pavlova, and Michel Fokine.

Petipa was born in Marseille. His father and brother were dancers. Petipa made his debut as a dancer at the age of 20. A leg injury slowed down his career and turned him toward choreography. Katy Matheson

Petit, *peh TEE,* **Roland** (1924-), is a French dancer and *choreographer* (creator of dances). After the end of World War II in 1945, he revitalized French ballet by creating a brilliantly stylish and theatrical dance style. Petit's best known work is *Carmen* (1949), which starred his wife, Renée "Zizi" Jeanmaire. He also choreographed such ballets as *Les Forains* (1945), *Le Jeune Homme et la Mort* (1946), and *Paradise Lost* (1967).

Petit was born in Villemomble. After dancing with the ballet of the Paris Opéra from 1939 to 1944, he co-founded the Ballets de Champs-Elysees in 1945. From 1948 to 1959, he was artistic director of the Ballets de Paris de Roland Petit. In 1966, he formed the Ballets de Roland Petit. In 1972, he became artistic director of the Ballet National de Marseille. He also choreographed films and stage revues. Dorothy Lourdou

Petit basset griffon vendéen, *puh TEE bah SAY gree FOHN vohn day OHN,* is a short-legged, rough-coated dog bred to hunt small game, especially hare and rabbit. The name is sometimes abbreviated *PBGV.* The breed originated in Vendée, a region of rough terrain in western France. It is a *scent hound,* which means it hunts by following the scent of the game animal.

The PBGV stands about 13 to 15 inches (33 to 38 centimeters) high at the shoulder and weighs from 30 to 42 pounds (14 to 19 kilograms). Its rough coat is mostly white with orange or gray markings. Its ears are long and narrow and covered by long hair, and it has a mustache and beard. The PBGV is alert, intelligent, and lively and can make a good pet.

Petit point, *PEHT ee poynt,* is a delicate form of embroidery usually sewed on fine mesh canvas. The term is also used to describe the finished canvas. Petit point is sometimes called *tent stitch* or *half stitch.*

The term *petit point,* which is French, means *small stitch* and refers to the tiny size of the stitches. These tiny stitches slant from left to right and are parallel to one another. The sewer uses a thin needle and fine thread.

Petit point is especially suited for highly detailed designs on such small objects as eyeglass cases, gloves, and handbags. The stitch is also used for embroidering larger canvas panels to decorate furniture seats and backs and canvas pieces that may be framed for display.

People have embroidered petit point since the Middle Ages. However, the term did not appear until the

etition of Right was a document written in 1628 by e English Parliament and presented to King Charles I. declared unconstitutional certain actions of the king, uch as levying taxes without the consent of Parliament, ousing soldiers in homes, setting up *martial law* (mili-ary government), and imprisoning citizens illegally.

Charles did not like the Petition of Right, but he ac-epted it because he knew of no other way to persuade arliament to vote the funds he had demanded. But he id not intend to carry out his part of the agreement. He ontinued to rule without consent of Parliament until his njust methods brought about his execution in 1649.

The Petition of Right had important results, even hough it did not accomplish its immediate aims. It de-lared, in effect, the supremacy of law over the personal vishes of the king. It also rejected the *divine right of ings,* the belief that monarchs get their right to rule di-ectly from God, rather than from the consent of their ubjects. The petition is a landmark in the history of con-titutional government in England. Charles Carlton

Petoskey stone, *puh TAHS kee,* is a rounded, pol-shed fragment of fossilized coral found near Petoskey, Aich. The fossils come from limestone deposits formed bout 350 million years ago.

The coral occurs in columnlike formations. When cut cross, each column has a six-sided shape within it, ac-ompanied by a pattern of lines that branches out from he center. This structure can be seen most clearly on a mooth, wet surface.

The natural action of water, or grinding and polishing y a craftworker, shapes the fossil into a gem prized by nineral collectors. In 1965, Petoskey stone became Aichigan's state stone. Donald F. Eschman

Petra, *PEE truh,* was an ancient city south of the Dead ea in what is now Jordan. It was an important trading center from the late 400's B.C. to the early A.D. 200's. The city stood on the overland trade route that linked Arabia and the Mediterranean Sea. The Nabataeans, a group of Arabian people, came to power in Petra in the 400's B.C. In A.D. 106, Roman forces conquered Petra and made it part of the Roman Empire. Petra prospered from A.D. 106 to the early 200's. The people built handsome tem-ples on the small plain there, and they cut deeply into the cliffs to make their houses. Petra had often been called the *rose-red city* because of its red stone build-ings and the red cliffs that surrounded it.

About A.D. 235, Petra suddenly stopped making coins, and Palmyra, a city in Syria, took over most of Petra's trade. Petra then became chiefly a religious center. It be-came a Christian city by the A.D. 300's. Muslims captured the city in the 600's. The Franks, a Germanic people, oc-cupied it during the Crusades, and held it until 1189. Soon after, the city was abandoned, and it fell to ruin (see **Jordan** [picture]). Mary Francis Gyles

Petrarch, *PEE trahrk* (1304-1374), was a great Italian lyric poet and scholar. His love poetry has had an unpar-alleled influence on world literature. He was also such a respected scholar that rulers and popes sought his serv-ices. Petrarch led in discovering the greatness of classi-cal writers and helped start the movement later called *humanism.* Such Latin writers as Cicero and Livy might be almost unknown today if Petrarch had not found their lost works buried in monastery libraries.

In his own day, Petrarch's Latin writings were consid-ered revivals of the Greek and Roman style of literature. His intimate knowledge of the classics led to his convic-tion that there is no essential conflict between classical and Christian thought. This conviction anticipated the spirit of the Renaissance.

Throughout his life, Petrarch composed poems of varying length in Italian to praise a beloved woman called Laura. Scholars are not certain that Laura really lived. At first, Petrarch saw in Laura a fleeting image of beauty which he never tired of describing. Eventually he added Christian dimensions to this image of beauty, re-flecting implications of human hopes, aspirations, and duties.

Petrarch wrote more than 400 poems in Italian. Of these, 366 form his *Canzoniere* (*Book of Songs*), on which his reputation rests. Petrarch divided the collec-tion into two parts. The first contains poems presumably written during Laura's lifetime and the second written after her death. In the first part, the reader senses a par-allel between the poet's attempts to define Laura and Apollo's pursuit of Daphne in the famous classical myth (see **Daphne**). In the second part, however, Laura as-sumes the role of a guide, leading her lover toward God and toward ultimate salvation.

The *Canzoniere* includes a roughly chronological his-tory of the poet's overwhelming passion for Laura and ends with a hymn to the Virgin Mary. The work ex-presses a haunting sense of the passage of time and of the vanity of earthly endeavors. It also shows an intense awareness of the conflict between spiritual and earthly values. The tone of the collection alternates bodily pleasure with spiritual love and religious feeling. The poems thus mirror an individual's uneasy condition as being capable of both the lowest depths and the great-est heights. Technically, Petrarch achieved new perfec-

tion in writing the sonnet and the ode, the chief literary forms in the *Canzoniere.* The work influenced such lyric poets as Pierre de Ronsard, Sir Philip Sidney, Luis de Góngora, John Donne, and William Shakespeare.

Petrarch was born Francesco Petracco in Arezzo. He spent most of his productive years in France where his father was in political exile. Richard H. Lansing

Petrel, *PEHT ruhl,* is one of a large group of ocean birds. They range over all the oceans of the world. Petrels seldom come near land except during the breeding season, or when they are blown ashore by storms. They usually nest in protected ledges or in burrows along the shore. Petrels may be black, gray, or white in color. They range from about 6 inches to 3 feet (15 to 91 centimeters) long.

There are many kinds of petrels, including the cahow, *diving-petrels, fulmars, shearwaters, and storm-petrels.* Some petrels feed by diving into the water. But most petrels fly close above the waves and pick up food from the surface. Storm-petrels, which are the smallest petrels, use their feet as paddles just below the surface of the water as they glide above it. They seem to be walking on top of the ocean. Sailors often call storm-petrels "Mother Carey's chickens." Most storm-petrels breed along the Pacific Coast of North America. One species also nests along the Atlantic Coast from Labrador to Maine.

Scientific classification. Petrels are in the family Procellariidae. Storm-petrels make up the subfamily Hydrobatinae.

Petrified forest, *PEHT ruh fyd,* is made up of tree trunks that were buried in mud, sand, or volcanic ash ages ago and have turned to stone. This action is caused by water that carries dissolved mineral matter. The water seeps through the mud and sand into the buried logs. There it fills the empty cells of the decaying wood with this matter until the structure has become solid stone. This stone shows many details of the original wood structure, especially under the microscope.

Petrified logs are buried in various rock formations from different geologic periods. These fossils represent the types of trees that grew during a certain period. Petrified forests have been found in many states, especially in the Western states and New York.

In the United States, the most famous petrified forest lies in northern Arizona, near the town of Adamana. It covers about 40 square miles (100 square kilometers), which have been set aside as the Petrified Forest National Park. Thousands of petrified logs may be seen lying about on the surface where water has washed away the rock in which they were buried. On the average, the logs measure 3 to 4 feet (0.9 to 1.2 meters) across and 60 to 125 feet (18 to 38 meters) long. Most of them have broken into many pieces and lie scattered about. Only a few logs are still whole and none of them stand upright. The logs were carried there by a flooded river perhaps around 225 million years ago. As they traveled down the river, they were stripped of their branches and leaves. Through the ages, many of the logs have become rainbow-colored. Thousands of people have visited Petrified Forest National Park to see this scenic display.

In life, the logs were the trunks of coniferous trees related to the Norfolk Island pine. Today they consist largely of quartz and opal, two forms of silica. Their yellow, red, purple, and black colorations were produced by impurities of the oxides of iron and manganese.

Petrochemicals, *PEHT roh KEHM uh kuhlz,* are chemicals made from petroleum or natural gas. They are among the most important materials used in industry. Manufacturers use petrochemicals in such products as detergents, fertilizer, medicines, paint, plastics, synthetic fibers, and synthetic rubber.

The basic materials of the chemical industry are the *primary petrochemicals.* They may be divided into three major groups, according to their chemical structure: (1) olefins, (2) aromatics, and (3) synthesis gas.

Important olefins include *ethylene, propylene,* and *butadiene.* Ethylene and propylene serve as important sources of industrial chemicals and plastics products. Butadiene is used in making synthetic rubber.

The chief aromatic petrochemicals include *benzene, toluene,* and *xylenes.* Benzene is used in the manufacture of dyes and synthetic detergents. Toluene is used in making explosives. Manufacturers use xylenes in making plastics and synthetic fibers.

Synthesis gas is a mixture of carbon monoxide and hydrogen. The petrochemicals *ammonia* and *methanol* are made from synthesis gas. Ammonia is used in making fertilizer and explosives. Methanol serves as a source for other chemicals.

How petrochemicals are made. Petroleum and natural gas consist chiefly of compounds of the elements hydrogen and carbon. These compounds are called *hydrocarbons.* Most petrochemicals contain carbon that comes from such hydrocarbon compounds.

One important method of producing olefin and aromatic primary petrochemicals is a process called *steam cracking.* In this process, hydrocarbons separated from natural gas or crude oil are mixed with steam in a tubular furnace and quickly heated to between 1,470 and 1,650 °F (800 and 900 °C). The hydrocarbons are thus broken down to simpler compounds, which then combine to form the desired petrochemicals. Primary petrochemicals, especially aromatics, are produced as by-products of petroleum refining.

Complex petrochemicals are made by combining two or more primary petrochemicals. For example, ethylene and benzene can be combined to form *ethylbenzene,* used to make synthetic rubber. Other complex petrochemicals include *polyethylene, polypropylene,* and *polyvinyl chloride.* Manufacturers use these petrochemicals in producing such plastics goods as car parts, electrical insulation, leatherlike clothing and luggage, and squeeze bottles.

History. The first chemical to be made from petroleum or natural gas was produced from natural gas in the United States in 1872. This chemical, *carbon black,* is now used as a reinforcing material in tires.

The widespread use of oil and gas to make chemicals began during the 1920's. Until that time, chemical companies used coal as a source of many chemicals. Then the companies began using petroleum and natural gas to produce the same chemicals because oil and gas were cheaper and easier to obtain than coal. Petrochemicals enabled manufacturers to cheaply produce such materials as plastics and synthetic fibers.

The use of petrochemicals increased rapidly during World War II (1939-1945). The armed forces used many products made from petrochemicals, including explosives and synthetic rubber.

Until the late 1900's, the United States, Japan, and the nations of Western Europe dominated the petrochemical industry. Many nations in the Middle East and Asia then began producing petrochemicals for export rather than merely exporting crude oil and natural gas. Developing and operating petrochemical facilities has helped these countries improve living standards for their people. Geoffrey E. Dolbear

Most petroleum comes from the earth as a liquid called *crude oil.* Different types of crude oil vary in color and thickness, ranging from a clear, thin fluid to a dark, tarlike substance. In some parts of the world, petroleum also occurs as a solid in certain sands and rocks.

Petroleum

Petroleum is one of the most valuable natural resources in the world. Some people call petroleum *black gold,* but it may be better described as the lifeblood of industrialized countries. Fuels made from petroleum provide power for automobiles, airplanes, factories, farm equipment, trucks, trains, and ships. Petroleum fuels also generate heat and electricity for many houses and business places. Altogether, petroleum provides nearly half the energy used in the world.

In addition to fuels, thousands of other products are made from petroleum. These products range from paving materials to drip-dry fabrics and from engine grease to cosmetics. Petroleum is used to make such items in the home as aspirins, carpets, curtains, detergents, phonograph records, plastic toys, and toothpaste.

Although we use a huge variety of products made from petroleum, few people ever see the substance itself. Most of it comes from deep within the earth as a liquid called *crude oil.* Different types of crude oil vary in thickness and color, ranging from a thin, clear oil to a thick, tarlike substance. Petroleum is also found in solid form in certain rocks and sands.

The word petroleum comes from two Latin words meaning *rock* and *oil.* People gave it this name because they first found it seeping up from the earth through cracks in surface rocks. Today, petroleum is often referred to simply as *oil,* and most of it is found in rocks beneath the earth's surface.

People have used petroleum for thousands of years. But few people recognized its full value until the 1800's, when the kerosene lamp and the automobile were invented. These inventions created an enormous demand for two petroleum fuels, kerosene and gasoline. Since about 1900, scientists have steadily increased the variety and improved the quality of petroleum products.

Petroleum, like other minerals, cannot be replaced after it has been used. People are using more and more petroleum each year, and the world's supply is rapidly running out. If present rates of consumption continue, petroleum may become scarce sometime in the mid-2000's.

Most industrialized nations depend heavily on imported petroleum to meet their energy needs. As a result of this dependence, oil-exporting countries have been able to use petroleum as a political and economic weapon by restricting exports to some of these nations. Oil exporters have also strained the economies of a large number of countries, particularly the poorer ones, by drastically increasing the price of petroleum.

To prevent a full-scale energy shortage, scientists are experimenting with artificial forms of oil and with other sources of fuel. But even if new energy sources appear quickly, people will have to rely on petroleum for many years. Conservation of oil has thus become urgent for

ery country. People now need to be just as inventive finding ways to conserve petroleum as they have een in finding ways to use it.

Uses of petroleum

Petroleum has a greater variety of uses than perhaps ıy other substance in the world. The reason petroleum ıs so many uses lies in its complicated molecular ructure. Crude oil is chiefly a mixture of many different *hydrocarbons,* which are molecules made up of the elements hydrogen and carbon. Some of these hydrocarbons are gaseous, and some are solid. Most of the hydrocarbons, however, form a liquid.

The mixtures of different hydrocarbons give special characteristics to the *fractions* (parts) of petroleum. Some fractions, such as gasoline and kerosene, are valuable in their natural liquid state. Others must be converted from one state to another or must be combined

with different substances before they can be used.

Various types of crude oil contain different amounts of certain fractions. *Light crudes* have large amounts of dissolved gases, gasoline, and other light fractions. Most *heavy crudes* have a high proportion of heavy oils and asphalt. All crude oil contains some substances in addition to hydrocarbons. These impurities, which include metallic compounds and sulfur, may make up as much as 10 per cent of some types of oil.

Petroleum refineries separate the various fractions and change them into useful products. Most crude oil is refined into gasoline, heating oil, and other fuels. The rest of the oil is converted chiefly into industrial raw materials and lubricants.

Petroleum as a fuel. Petroleum fuels ignite and burn readily and produce a great amount of heat and power in relation to their weight. They are also easier to handle, store, and transport than such other fuels as coal and wood. Petroleum supplies about 43 per cent of the energy consumed in the United States. It is the source of nearly all the fuels used for transportation and of many fuels used to produce heat and electricity.

Fuels for transportation include gasoline, diesel fuel, and jet fuel. About 45 per cent of all crude oil is refined into gasoline, about 7 per cent into diesel fuel, and about 7 per cent into jet fuel.

Gasoline is classified into regular, premium, and aviation grades, according to how smoothly it burns in an engine. Most motor vehicles and all piston-engine airplanes use gasoline. Diesel fuel requires less refining and is cheaper than gasoline. Nearly all trains, ships, and large trucks use diesel fuel. Jet airplanes burn jet fuel, which is either pure kerosene or a mixture of gasoline, kerosene, and other fuels.

Fuels for heating and energy production account for about 26 per cent of all refined petroleum. Such fuels may be classed as *distillate oils* or *residual oils.* Distillate oils are lighter oils, most of which are used to heat houses and small business places. Residual oils are heavier, thicker oils. They provide power for electric utilities, factories, and large ships. Residual oils are also used to heat large buildings.

Many people who live on farms or in mobile homes use *liquefied petroleum gas* (LPG) for heating and cooking. LPG consists chiefly of butane and propane gases that have been converted under pressure into liquids. LPG is used in industry for cutting and welding metals and on farms for operating various kinds of equipment.

Petroleum as a raw material. About 13 per cent of petroleum fractions serve as raw materials in manufacturing. Many of these fractions are converted into *petrochemicals,* which make up more than a third of all the chemicals produced in the United States. Petrochemicals are used in manufacturing cosmetics, detergents, drugs, fertilizers, insecticides, plastics, synthetic fibers, and hundreds of other products.

By-products of petroleum refining are also used as raw materials in certain industries. These by-products include asphalt, the chief roadbuilding material, and wax, an essential ingredient in such products as candles, milk cartons, and furniture polish.

Other uses of petroleum. Such products as lubricants and specialized industrial oils account for about 2 per cent of petroleum production. Lubricants reduce friction between the moving parts of equipment. They range from the thin, clear oil used in scientific instruments to the heavy grease applied to aircraft landing gear. Specialized industrial oils include *cutting oils* and *electrical oils,* which are used in manufacturing.

Where petroleum is found

Petroleum is found on every continent and beneath every ocean. But present-day techniques enable petroleum engineers to *recover* (bring to the surface) only about a third of the oil in most deposits. These recoverable amounts of petroleum are called *reserves.*

Petroleum experts estimate that the world's oil reserves total about 1 trillion barrels. Some geologists predict that additional reserves will be discovered, particularly in China, on Canadian islands in the Arctic Ocean, and in offshore seabeds. However, many experts think that most of the major oil fields have already been found. They believe that world reserves are more likely to be increased by better methods of recovery than by new discoveries of oil.

The Middle East has about 67 per cent of the world's oil. Its reserves total about 660 billion barrels. Saudi Arabia has about 258 billion barrels, or about a fourth of the world's reserves. Most of Saudi Arabia's petroleum lies in areas along the Persian Gulf. Abu Dhabi, Iran, Iraq, and Kuwait each have about a 10th of the total world petroleum reserves.

Europe, including the Asian part of Russia, has about 7 per cent of the world's oil supply. Russia, with about

7 billion barrels, has the largest reserves in the region. Most of these reserves lie west of the Ural Mountains, though there are several large oil fields in Siberia. The only other major European reserves, which amount to about 17 billion barrels, are beneath the North Sea. These reserves belong chiefly to Great Britain and Norway.

Latin America has about 120 billion barrels of petroleum reserves, or 12 per cent of the world's total. Venezuela has the largest reserves in the region, about 59 billion barrels. Huge deposits of heavy oil lie north of the Orinoco River in eastern Venezuela. The other major oil region in Venezuela is the Lake Maracaibo Basin in the northwestern part of the country. Light and medium grades of crude oil lie in this area. Mexico has the second largest reserves in Latin America, about 52 billion barrels. Most of Mexico's reserves lie in the eastern part of the country, along the Gulf of Mexico. Other Latin American countries with important petroleum deposits include Argentina and Brazil.

Africa possesses about 60 billion barrels of oil, or 6 per cent of the world's reserves. Most of the oil lies in Libya, Algeria, and other countries in northern Africa. Libya's reserves of about 23 billion barrels rank as the region's largest. South of the Sahara, large amounts of oil have been found only in Nigeria, which has about 17 billion barrels.

Asia, excluding the Asian part of Russia and the Middle East, has about 50 billion barrels of oil, or 5 per cent of the world's reserves. About half these reserves lie in China. China's largest oil field is at Daqing in Manchuria. Other major Chinese deposits lie on the Shandong Peninsula and in the province of Xinjiang. Indonesia, with about 11 billion barrels, has the second largest reserves in the Far East.

The United States and Canada have about 32 billion barrels of oil, which amounts to 3 per cent of the world total. The United States has about 26 billion barrels of petroleum. Most of these reserves lie in Texas, Louisiana, California, Oklahoma, and Alaska. In time, U.S. reserves may be increased by oil produced from *oil shale,* a type of rock that is plentiful in Colorado, Wyoming, and Utah. Oil shale contains *kerogen,* a waxy substance that yields oil when heated.

Most of Canada's 6 billion barrels of oil lie in the province of Alberta. Saskatchewan, British Columbia, and Manitoba also have oil fields. In addition, geologists believe that Canada has the world's largest deposits of

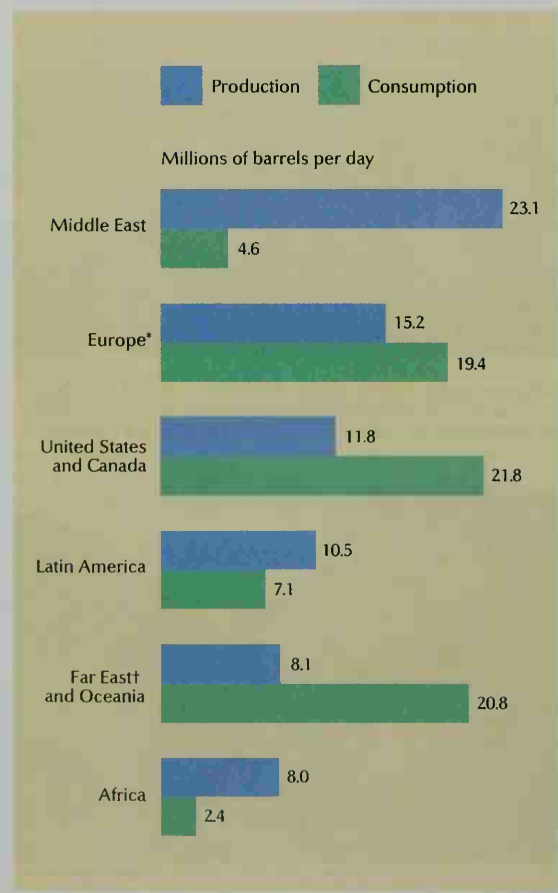
bituminous sands, or *tar sands* (sands soaked with an oil-producing substance). These deposits, which are estimated to contain up to a trillion barrels of oil, lie along the Athabasca River in Alberta. Production of oil from the sands began in 1967.

How petroleum was formed



Most geologists believe petroleum was formed from remains of organisms that died millions of years ago. This *organic theory* of petroleum formation is based on the presence of certain carbon-containing substances in oil. Such substances could have come only from once-living organisms. The process that produced petroleum also produced natural gas. Thus, natural gas is often found in association with crude oil or dissolved in it.

According to the organic theory, water covered much more of the earth's surface in the past than it does today. Masses of tiny organisms lived in shallow water or drifted around near the surface in the open ocean. As these organisms died, their remains settled to the bottom of the ocean and became trapped in *sediments* (particles of mud, sand, and other substances). The sediments piled up and became buried below the surface of the ocean floor.

As the sediments became buried deeper and deeper, they were subjected to increasingly high temperatures and pressures, and so were compressed to form *sedimentary rock.* These conditions caused the rock to go through chemical processes that resulted in the formation of a waxy substance called *kerogen.* Kerogen separates into a liquid (oil) and a gas (natural gas) when it is heated to temperatures above about 212 °F (100 °C). But if the oil becomes buried too deeply and is exposed to temperatures higher than about 400 °F (200 °C), the bonds holding the large, complex oil molecules together weaken and the oil decomposes. The temperature range in which oil can form is called the *oil window.* At temperatures below this range, little oil forms. At great depths, where temperatures are high, most oil decomposes.

World production and consumption of petroleum

This graph shows the amounts of petroleum produced and used in various regions of the world. The Middle East produces about five times as much petroleum as it consumes. However, most regions consume more oil than they produce.

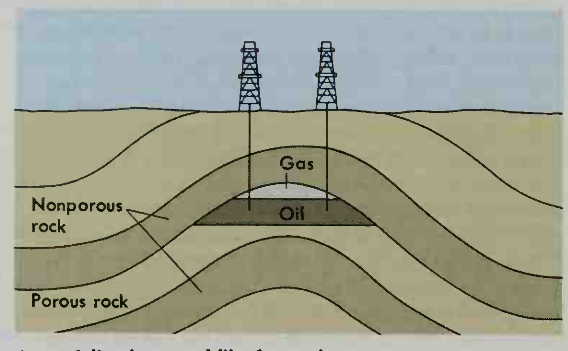
Over time, the oil and gas moved upward through ıtural passageways in the rock. These passageways inıded cracks and tiny holes known as *pores.* Geologists lieve this movement may have been caused by the esence of water in the rock. Water, which is more nse than oil, could have pushed the oil upward. Anıer possible cause was the weight of the overlying ers of rock, which would tend to squeeze the oil into les and cracks in the rock.

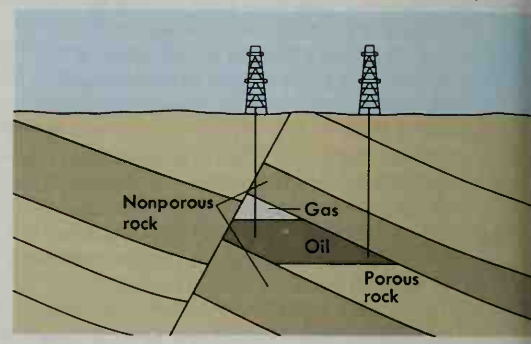
Oil and gas escaped to a type of rock called *reservoir ck.* Such rock has two characteristics that enable fluids move through it: (1) porosity and (2) permeability. rosity is the presence of small openings, or pores. rmeability means that some of the pores are connect- by spaces through which fluids can move. Oil and s moved upward through the connected pore spaces itil they reached an impermeable layer of rock. They ntinued to escape along the underside of the impereable layer until that layer formed some sort of threemensional *trap.* Later, shifts in the earth's crust caused the oceans to draw back. Dry land then appeared over many reservoir rocks and traps.

The most common types of petroleum traps are *anticlines, faults, stratigraphic traps,* and *salt domes.* An anticline is an archlike formation of rock under which petroleum may collect. A fault is a fracture in the earth's rocky outer shell. Rock can shift along a fault, moving an impermeable layer of rock next to a permeable one that contains oil. Most stratigraphic traps consist of layers of impermeable rock that surround oilbearing rocks. In a salt dome, a cylinder- or cone-shaped formation of salt pushes up through sedimentary rocks, causing the rocks to arch and fracture in its path. Petroleum may accumulate above or along the sides of such a formation.

Most reservoirs and traps lie deep beneath the surface of the earth. However, some reservoirs have formed near the surface, and others have been shifted upward by changes in the earth's crust. Oil from these shallow deposits may reach the surface as *seepages* (trickles) or springs. In some places, such as Venezuela



This map locates the world's major deposits of crude oil, oil sands, and oil shale. It also locates the principal oil-producing regions and areas where oil might be produced. Oil is found on every continent and in many offshore seabeds. But about two-thirds of the world's oil lies in the Middle East. Saudi Arabia is the world's largest oil producer. Possible oil-producing areas include the Arctic Ocean and Australia's offshore seabeds.



Where petroleum is found

Most crude oil lies in underground formations called *traps.* In a trap, petroleum collects in the pores of certain kinds of rock. Gas and water are also present in most traps. The most common types of traps are *anticlines, faults, stratigraphic traps,* and *salt domes.*

and the island of Trinidad, enough oil has collected at the surface to form a lake.

Today, the organic matter in some sedimentary deposits is being subjected to conditions of pressure, heat, and bacterial action similar to those that formed oil ages ago. But it takes millions of years for useful amounts of oil to develop. People are consuming petroleum much faster than it is being formed.

Exploring for petroleum

Before about 1900, petroleum prospectors could do little more than look for oil seepages and hope for luck. Their equipment consisted chiefly of a pick, a shovel, and possibly a *divining rod,* a forked stick that some people believed could magically locate oil or water. During the 1900's, however, petroleum exploration developed into a science. Today, prospectors use a variety of complicated instruments and are likely to be *oil geologists* or *geophysicists.*

Geological studies. Oil geologists study rock formations on and below the earth's surface to determine where petroleum might be found. They usually begin by selecting an area that seems favorable to the formation of petroleum, such as a sedimentary basin. Geologists then make a detailed map of the surface features of the area. They may use photographs taken from airplanes and satellites in addition to their ground-level observations, particularly if the area is difficult to cover on foot. The geologists study the map for signs of possible oil traps. For example, the appearance of a low bulge on a[n] otherwise flat surface may indicate the presence of a sa[lt] dome, a common petroleum trap.

If the site looks promising, oil geologists may obtain *cores,* which are cylindrical samples of the underground layers of rock. The geologists analyze the cores for chemical composition, structure, and other factors that relate to the formation of petroleum.

Oil geologists also study *well logs.* A well log is a record of the rock formations encountered during drilling. Well logs describe the depth, porosity, and fluid content of the rocks. Oil geologists use this information to estimate the location and size of possible deposits in the area surrounding the wells.

Geophysical studies. Geophysicists provide oil geol[-]ogists with detailed information about underground an[d] underwater rock formations. Geophysicists can locate geological structures that may contain oil with the aid o[f] special instruments. The most widely used instruments are (1) the gravimeter, (2) the magnetometer, and (3) the seismograph.

The gravimeter (pronounced *gruh VIHM uh tuhr*), or gravity meter, measures the pull of gravity at the earth's surface. Different kinds of rocks have different effects o[n] gravity. For example, nonporous rocks tend to increase gravitational pull, and porous rocks tend to decrease it. Thus, low readings on a gravimeter may show the pres-

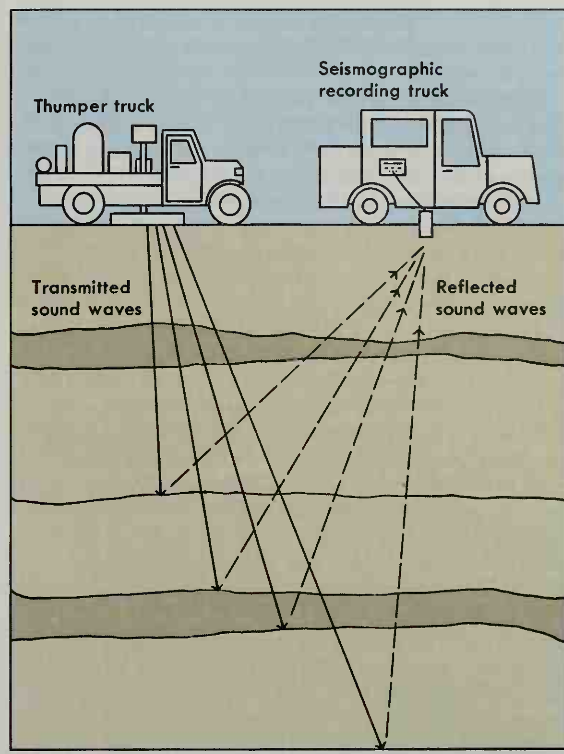
ce of possibly oilbearing, porous layers of rock. Gra-
neters are particularly effective in detecting salt
mes because salt decreases the pull of gravity more
n most rocks do.

The magnetometer (MAG *nuh TAHM uh tuhr*) records
anges in the earth's magnetic field. The magnetic pull
the earth is affected by the rocks beneath its surface.
dimentary rocks generally have lower magnetism
n other types of rock, which may contain iron and
ner magnetic substances. This difference in magnetic
ll enables geophysicists to identify sedimentary rock
t may contain oil. In addition, magnetic pull is af-
ted by structural irregularities, such as anticlines and
lts. Magnetometers may thus detect some petroleum
ps.

The seismograph (*SYZ muh graf*) measures the
eed of sound waves traveling beneath the earth's sur-
e. This speed depends on the type of rock through
ich the sound waves move. Geophysicists can use the
eeds and travel times to determine the depth and
ape of many potential traps.

In a seismographic survey, geophysicists may set off a
all explosion at or just below the earth's surface. The
und waves generated by the explosion travel to un-
rground layers of rock and bounce back to the sur-
e. The seismograph records how long it takes the
und waves to reach the surface. Many geophysicists
e a system called *vibroseis* (*vy BROH see ihs*) to elimi-
te the environmental risks of using explosives. In this
stem, sound waves are produced by a huge vibrator
at repeatedly strikes the earth. The vibrator is
ounted on a special truck called a *thumper truck.*

Geophysicists also conduct seismographic surveys of
shore areas. They send an electronic pulse or
mpressed-air discharge from a ship into the water.
e resulting sound waves are reflected from underwa-
formations to seismographic equipment that is
wed behind the ship.



By means of a technique called *bright spot technol-
y,* geophysicists can use seismographs to detect the
esence of fluids in underground and underwater rock
rmations. This technique involves the use of highly
nsitive recorders that pick up changes in the *ampli-
de* (height) of sound waves. Sound waves change in
plitude when they are reflected from rocks that con-
n gas and other fluids. Such changes appear as irreg-
arities, called *bright spots,* on the sound wave pat-
ns recorded by the seismograph.

Drilling an oil well

Drilling for petroleum is nearly always an enormous
mble. Most geological and geophysical studies indi-
te the places where petroleum might have accumu-
ed. However, there is less than a 10 per cent chance
at oil is actually present in those places. There is only a
er cent chance that it is present in those places in
mmercially useful amounts. Many *dry holes* may be
illed before a producing well is *brought in* and the oil
gins to flow.

Preparatory measures take place both on and off
e drilling site. They include (1) obtaining leases and
rmits, (2) preparing the site, and (3) rigging up.

Obtaining leases and permits. In the United States,
companies must deal with the owner of a site—or

WORLD BOOK illustration by Steven Liska

Sound waves can help find oil. A method called *vibroseis* operates on the principle that the speed of sound waves varies according to the type of rock through which they travel. Vibroseis thus enables geophysicists to locate rocks that may contain oil. In this method, a *thumper truck* produces sound waves. Another truck holds a *seismograph,* an instrument that records the time in which underground rocks reflect the waves to the surface.

with the government if the site is on public property—for permission to drill. Most companies obtain a *mineral lease,* which gives them the right to drill wells and to produce oil and gas on the site. In return, the owner generally receives *royalties* (shares of the income) from any oil and gas recovered.

After obtaining a mineral lease, an oil company must get drilling permits from the federal, state, and local governments. Before such permits are issued, a company has to meet certain requirements. In most cases, for example, a company must submit studies of the effect drilling will have on the environment. A company must also show how it intends to conserve natural resources and prevent waste.

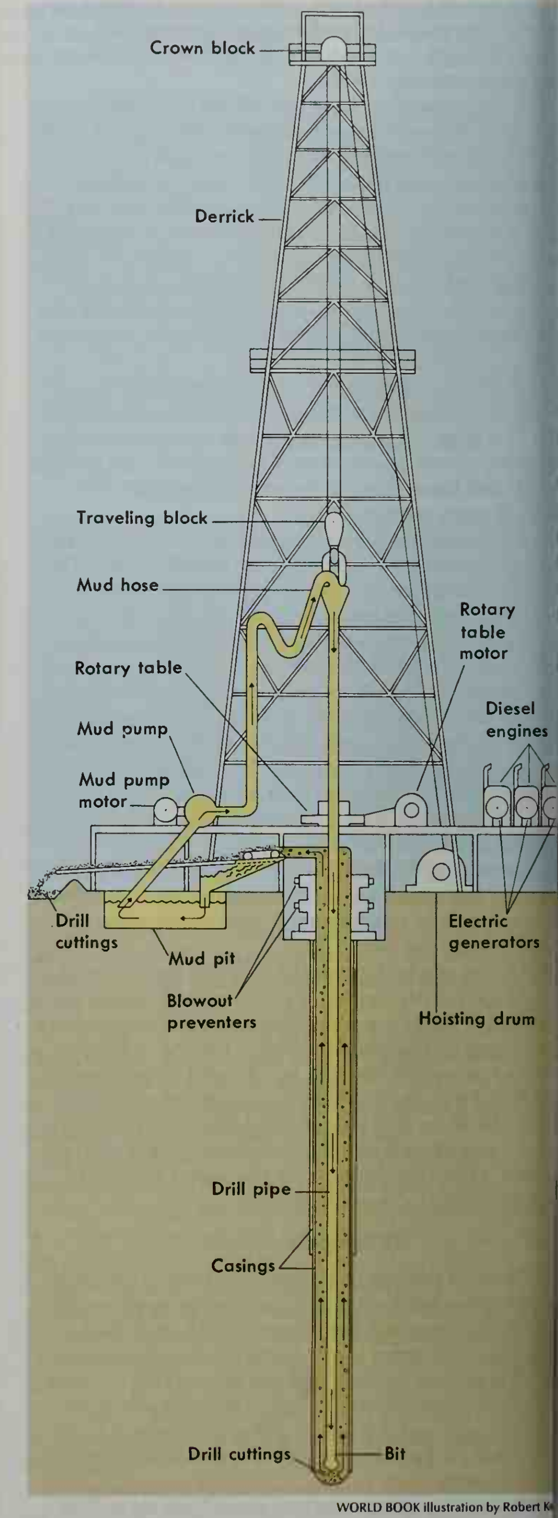
In Canada, most of the mineral rights for land and offshore areas are owned by the federal or provincial governments. Oil companies therefore obtain most mineral leases from the government. The companies are then required by law to begin certain exploratory work on the leased area within a specified period.

Preparing the site. A drilling site must be flat and free of trees and brush to make room for drilling operations. In most locations, bulldozers are used to clear and level the ground. If an area has rough terrain or a harsh climate, additional preparation may be required. On Alaska's North Slope, for example, drilling sites had to be reinforced with gravel and wood. If these measures had

not been taken, the heat generated by the drilling equipment might have thawed the frozen soil and caused the wells to collapse.

Roads must be built to the drilling site. The site must also have a power plant and a water supply system. If the location is far from a city or town, or offshore, living quarters may have to be set up for the crew.

After the drilling site has been prepared, the construction crew brings in the *rig,* which consists chiefly of drilling equipment and a derrick. The rig may be transported by truck, bulldozer, barge, or aircraft, depending on the location of the site.



Rigging up is the process of setting up and connecting the various parts of the rig. First, the construction crew erects the derrick over the spot where the well is to be drilled. Derricks serve mainly to hold the hoisting machinery and other drilling equipment. The hoisting machinery, which includes pulleys, reels, and heavy wire, lowers the drill into the well hole and hoists it out. Derricks range in height from 80 to 200 feet (24 to 61 meters), depending on the estimated depth of the oil. Most construction crews use a *jackknife derrick,* which consists of two or more sections that can be easily transported and assembled.

Next, the crew installs the engines that power the drill and other machinery on the rig. The workers also assemble the various pipes, tanks, pumps, and other drilling equipment. After the drill is attached to the hoisting machinery, the well hole can be *spudded in* (started) by any of several methods of drilling.

Methods of drilling. The first oil crews in the United States used a drilling technique called *cable-tool drilling,* which is still used for boring shallow holes in hard rock formations. Today, however, most American crews use a faster and more accurate method called *rotary drilling.* On sites where the well must be drilled at an angle, crews use a technique called *directional drilling.* In addition, petroleum engineers are testing a variety of methods to increase the depth of oil wells and reduce the cost of drilling operations.

Cable-tool drilling is a simple process. It works much as a chisel is used to cut wood or stone. In this method, a steel cable repeatedly drops and raises a heavy cutting tool called a *bit.* Bits may be as long as 8 feet (2.4 meters) and have a diameter of 4 to $12\frac{1}{2}$ inches (10 to 31.8 centimeters). Each time the bit drops, it drives deeper and deeper into the earth. The sharp edges of the bit break up the soil and rock into small particles. From time to time, the workers pull out the cable and drill bit and pour water into the hole. They then scoop up the water and particles at the bottom of the hole with a long steel pipe known as a *bailer.* The crew for cable-tool drilling generally consists of a *driller,* who operates the equipment on the rig, and a *tool dresser,* who sharpens the bit and does other jobs.

Rotary drilling, like cable-tool drilling, works on a simple principle. The drill bores through the ground much as a carpenter's drill bores through wood. The bit on a rotary drill is attached to the end of a series of connected pipes called the *drill pipe.* The drill pipe is rotated by a turntable on the floor of the derrick. The pipe is lowered into the ground. As the pipe turns, the bit bores through layers of soil and rock. The drilling crew adds lengths of pipe as the hole becomes deeper.

WORLD BOOK illustration by Robert K

A rotary-drilling rig includes a derrick and the machinery that raises and lowers the drilling equipment. As the *drill pipe* is lowered, it is turned by a *rotary table.* The *bit* at the end of the drill pipe bores through the earth. Mud is pumped through the well to clean the bit and bring up *cuttings* (pieces of rock).

The drill pipe is lowered and raised by a hoisting ıechanism called the *draw works,* which operates ɔmewhat like a fishing rod and reel or a pair of pulleys. teel cable is unwound from the *hoisting drum,* a kind f reel. The cable is then threaded through two *blocks* ets of pulleys)—the *crown block,* at the top of the rig, ıd the *traveling block,* which hangs inside the derrick. ıe workers attach the upper end of the drill pipe to the aveling block with a giant hook. They can then lower ıe pipe into the hole or lift it out by turning the hoisting rum.

During rotary drilling, a fluid called *drilling mud* is umped down the drill pipe. It flows out of the openıgs in the bit and then back up between the pipe and ıe wall of the hole to just below the derrick floor. This ɔnstantly circulating fluid cools and cleans the bit and ırries *cuttings* (pieces of soil and rock) to the surface. ıus, the crew can drill continuously without having to ail out the cuttings from the bottom of the well. The rilling mud also coats the sides of the hole, which elps prevent leaks and cave-ins. In addition, the presıre of the mud in the well reduces the risk of *blowouts* ıd *gushers,* which are caused by the sudden release of ressure in a reservoir. Blowouts and gushers may deroy the rig and waste much oil.

The drilling crew changes the bit when it becomes ull or if a different type of bit is needed. Different bits e used for hard and soft rocks. Each time the workers ıange the bit, they must pull out the entire drill pipe, hich may be longer than 25,000 feet (7,620 meters). As ıe drill pipe is raised from the well, the crew disconnects the lengths of pipe and stacks them inside the derrick. After the new bit has been attached, the workers lower the pipe back into the hole.

Most rotary-drilling crews consist of a *driller,* one or more *derrickmen,* and several workers known as *roughnecks.* Crews work around the clock, rotating in 8- or 12-hour shifts called *tours* (pronounced *TOW uhrz*).

Directional drilling. In cable-tool drilling and most rotary drilling, the well hole is drilled straight down from the derrick floor. In directional drilling, the hole is drilled at an angle. Drilling crews may use special devices called *turbodrills* and *electrodrills.* The motors that power these drills lie directly above the bit and rotate only the lower section of the drill pipe. Such drills enable drillers to guide the bit along a slanted path. Drillers may also use tools known as *whipstocks* to drill at an angle. A whipstock is a long steel wedge grooved like a shoehorn. The wedge is placed in the hole with the pointed end upward. The drilling path is slanted as the bit travels along the groove of the whipstock.

Many crews adopt directional drilling to drill more than one well at a site. The method is also used if a well cannot be drilled directly over an oil deposit. For example, oil lay beneath the State Capitol in Oklahoma City. By means of directional drilling, a hole was drilled to the oil from 400 feet (120 meters) away.

Experimental methods of drilling include the use of electricity, intense cold, and high-frequency sound waves. Each of these methods is designed to shatter the rocks at the bottom of the hole. Petroleum engineers are also testing a drill that has a bit with a rotating surface.

Directional drilling

In directional drilling, an oil well is drilled at an angle rather than straight down. Crews use such tools as *whipstocks* and *turbodrills* to guide the bit along a slanted path. This method is often used in offshore operations because many wells can be drilled directionally from one platform.

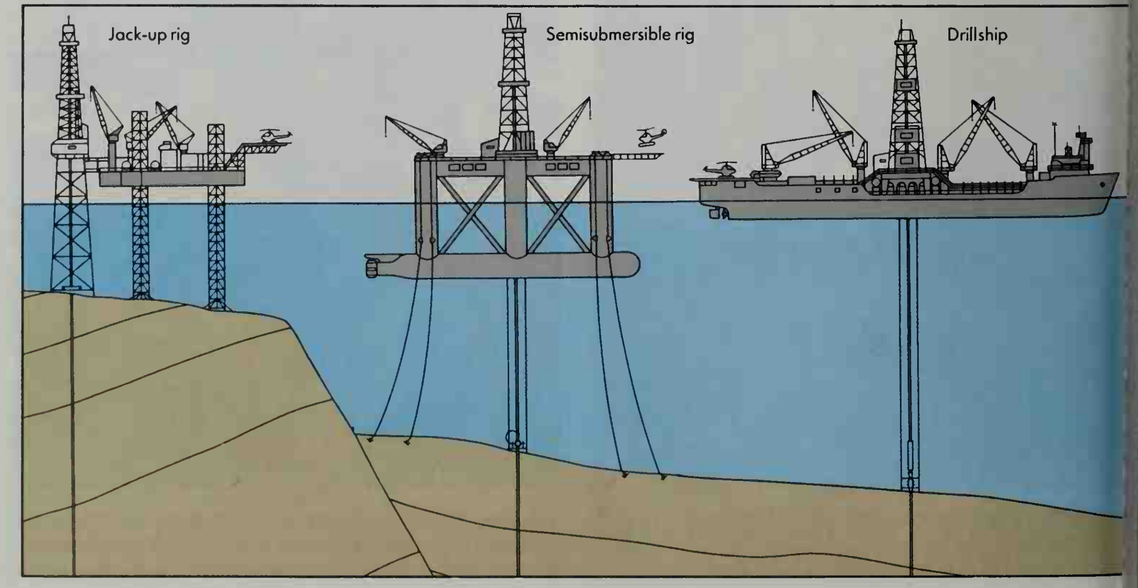
By means of remote control, drillers could rotate the bit to expose a new drilling surface. Such a bit would eliminate the need to pull the drill pipe out of the hole each time the bit is changed.

Offshore drilling is much more expensive and dangerous than drilling on land. The average offshore rig costs 10 times more than a land rig. All the equipment and the crew must be brought to the site by helicopter or ship. In such waters as the Arctic Ocean and the North Sea, rigs may be damaged by storms or floating blocks of ice. But as the number of land reserves declines, the importance of offshore wells increasingly outweighs their higher costs and risks.

Drilling an offshore well is similar to drilling a well on land. The parts of the drilling rig are the same. But an offshore rig must be mounted on something that can be taken to sea. Most exploratory wells are drilled from such movable rigs as *jack-up rigs, semisubmersible rigs,* or *drillships.* A structure called a *fixed platform* is used for oil production.

Jack-up rigs are commonly used in water depths of up to 200 feet (60 meters). But some jack-up rigs can be used in depths of up to 350 feet (110 meters). The rig rests on a floating platform attached to steel legs that can be jacked up or down. To move the rig, workers lower the platform into the water and jack up the legs off the ocean floor. Boats generally tow the rig to the new drilling site. There, the legs are again lowered to the ocean floor, and the floating platform is jacked up clear of the water's surface.



Semisubmersible rigs are used in intermediate water depths—that is, up to 4,000 feet (1,200 meters). This type of rig has legs filled with air, enabling it to float above the surface of the ocean. Anchors hold the rig in place.

Drillships are used in water depths of up to 8,000 feet (2,400 meters). Anchors cannot be used at such depths,

Offshore drilling

Most exploratory offshore wells are drilled from *jack-up rigs, semisubmersible rigs,* or *drillships.* A jack-up rig, which can be raised or lowered to various heights, has legs that rest on the ocean floor. A semisubmersible rig floats on cylindrical legs filled with air. A drillship has drilling equipment mounted on its deck, and a special opening through which the drill pipe is lowered.

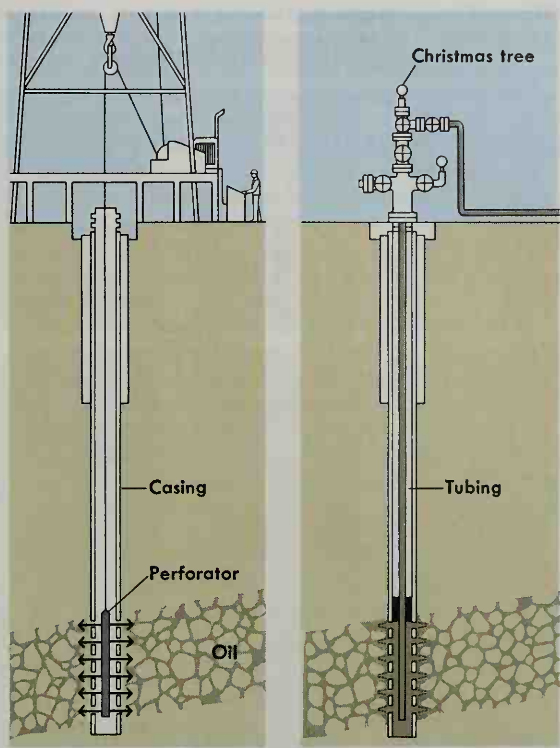
WORLD BOOK illustration by Robert Keys

a drillship must use precise navigational procedures to maintain its position above the well site. The derrick and other drilling equipment are mounted on the deck, and the drill pipe is lowered through an opening in the bottom of the ship. Drillships are extremely expensive to operate.

Fixed platforms, also known as *production platforms,* are generally built and installed only after exploratory drilling has uncovered enough petroleum reserves to justify their enormous expense. Most fixed platforms are used in shallow water, but some can be used in water deeper than 1,000 feet (300 meters).

Fixed platforms are built in segments that are carried by barge to the production site. Cranes guide the bottom segment to the ocean floor and position it over the site. Huge stakes called *piles* secure it to the ocean floor. The second segment fits on top of the bottom segment. Most fixed platforms have two segments, but some have three. The top of the uppermost segment serves as the base for the drilling. As many as 42 wells can be drilled in various directions from a fixed platform.

Well testing. Drilling crews try to determine as quickly as possible whether they are working on a productive site or a dry hole. During drilling, they continually examine the cuttings—the pieces of rock brought up by the drilling mud—for evidence of petroleum. When drilling reaches the depth of possible deposits, the crew may conduct several tests for oil. These tests include *coring, logging,* and *drill stem testing.*



In coring, the drill bit is replaced with a *coring bit.* This bit cuts out a cylindrical sample of soil and rock, which is brought to the surface for analysis. Logging involves lowering measuring instruments called *sondes* into the well hole. They transmit information about the composition, porosity, fluid content, and other characteristics of the underground rock. In the drill stem test, a device that takes samples of fluids and measures their pressure is lowered into the hole.

If the test results are negative, the drilling crew may plug the well with cement and abandon it. If the tests show evidence of petroleum, the crew reinforces the well hole with steel pipe called *casing.*

Casing is a kind of protective lining for the well hole. It consists of heavy steel pipe that ranges in diameter from $2\frac{7}{8}$ to 20 inches (7.3 to 51 centimeters). The lengths of pipe are held in place with cement. Casing helps prevent leaks and cave-ins during both the drilling stage and the production stage of the oil well. As an additional safeguard, nearly all drilling crews install one or more *blowout preventers* at the top of the casing. These devices consist of giant valves that close off the casing if pressure builds up in the well.

To install casing, drilling crews remove the drill pipe and lower the casing into the well hole. They then pump wet cement down the casing and cover the cement with a special plug that can be drilled through. While the cement is still wet, they pump mud into the casing. The mud pushes the plug to the bottom of the casing. The cement is thus forced up into the space between the well hole and the outside of the casing from the bottom of the hole to the surface. After the cement hardens, workers can continue to drill through the plug.

Completing the well means bringing the well into production. This operation is carried out in several

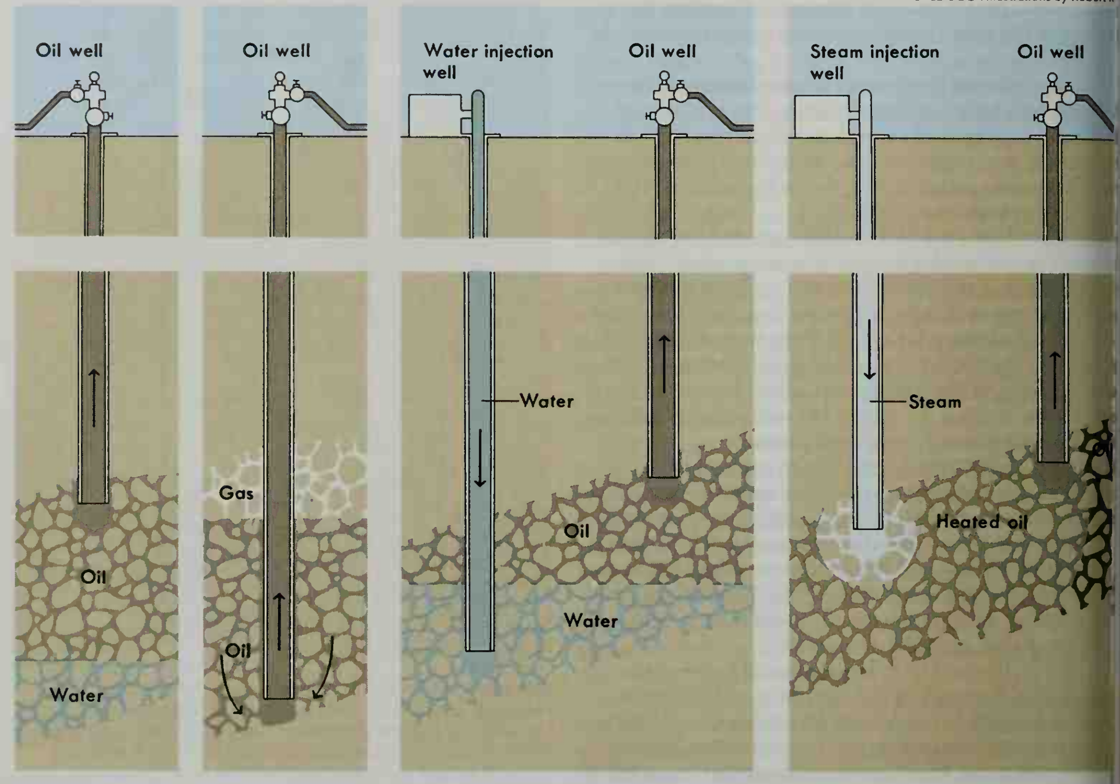
Completing a well. After lining the well hole with pipes called *casing,* the crew lowers an instrument called a *perforator* into the well. The perforator punches holes in the casing through which oil can enter, *left.* Then the crew installs the *tubing,* a string of smaller pipes that conducts the oil to the surface; and a *Christmas tree,* a set of valves that controls the flow of oil, *right.*

steps. First, the drilling crew lowers an instrument called a *perforator* into the casing to the depth of the oilbearing zone. The perforator fires special bullets or explosive charges into the casing, punching holes through which the oil can enter. The crew then installs the *tubing,* which is a string of smaller pipes that conducts oil to the surface. Tubing is used because the casing is generally too wide to maintain the fluid velocity necessary to keep the oil flowing upward. Tubing is also easier to repair and replace than casing.



One final step in completing a well is to assemble a group of control valves at the upper end of the casing and tubing. This valve system is known as a *Christmas tree* because of its many branchlike fittings. It controls the flow of oil to the surface. In some wells, more than one oilbearing zone is found. The crew then installs separate tubing and control valves for each zone. Such operations are called *multiple completion wells.*

Recovering petroleum

Petroleum is recovered in much the same way as underground water is obtained. Like certain types of water wells, some oil wells have sufficient natural energy to bring the fluid to the surface. Other oil wells have too little energy to produce oil efficiently, or they lose most of their energy after a period of production. In these wells, additional energy must be supplied by pumps or other artificial means. If natural pressure provides most of the

How oil is recovered A tremendous amount of energy is needed to bring oil to the surface. This energy may come from the natural pressure in a reservoir or from various artificial means. Depending on the source of energy, the process is called (1) primary recovery, (2) secondary recovery, or (3) tertiary recovery.

WORLD BOOK illustrations by Robert K

Primary recovery depends chiefly on two types of natural energy in a reservoir, *water drive* and *gas drive.* If oil production reduces some of the pressure underground, water or gas in the reservoir may drive the oil into the well.

Secondary recovery consists of replacing the natural energy in a reservoir. *Waterflooding,* one of the most widely used methods, involves injecting water into the reservoir. The water displaces the oil and causes it to flow into the well.

Tertiary recovery includes a number experimental methods of bringing oil to the surface. In one such method, steam injected into the reservoir. The steam heats the oil and makes it thinner, enabling it to flow more freely into the we

energy, the recovery of petroleum is called *primary recovery.* If artificial means are used, the process is known as *enhanced recovery.*

Primary recovery. The natural energy used in recovering petroleum comes chiefly from gas and water in reservoir rocks. The gas may be dissolved in the oil or separated at the top of it in the form of a gas cap. Water, which is heavier than oil, collects below the petroleum. Depending on the source, the energy in the reservoir is called (1) solution-gas drive, (2) gas-cap drive, or (3) water drive. Solution-gas drive brings only small amounts of oil to the surface. Most wells that have no natural energy other than solution-gas drive require supplementary forms of energy. Gas-cap drive and water drive, on the other hand, may result in the production of large quantities of petroleum.

Solution-gas drive. The oil in nearly all reservoirs contains dissolved gas. The effect production has on this gas is similar to what happens when a bottle of champagne is opened. The gas expands and moves toward the opening, carrying some of the liquid with it.

Gas-cap drive. In many reservoirs, gas is trapped in a cap above the oil as well as dissolved in it. As oil is produced from the reservoir, the gas cap expands and drives the oil toward the well.

Water drive. Like gas, water in a reservoir is held ir place mainly by underground pressure. If the volume water is sufficiently large, the reduction of pressure th occurs during oil production will cause the water to e pand. The water will then displace the petroleum, forc ing it to flow into the well.

Enhanced recovery includes a variety of methods designed to increase the amount of oil that flows into producing well. Depending on the stage of productio in which they are used, these methods are generally classified as either *secondary recovery* or *tertiary* (thir level) *recovery.*

Secondary recovery, also called *pressure maintenance,* consists of replacing the natural drives in the r ervoir. This form of recovery may involve injecting ga or water into the reservoir from additional wells drille near the producing well.

Although secondary recovery has nearly tripled the amount of recoverable oil, about two-thirds of the petroleum in most reservoirs remains below the surface after production. Petroleum engineers are testing tec

ques of tertiary recovery to bring more oil to the sur-
ce. One such technique uses heat to thin the oil and so
ake it flow more freely into the well. This heat may
me from injections of steam or from burning some of
e petroleum in the reservoir.

Transporting petroleum

After crude oil reaches the surface, natural gas is sep-
ated from the oil. The gas is then sent to a processing
ant or directly to consumers. Water and sediment are
moved from the oil, which is then stored in tanks or
nt to a refinery. From the refinery, petroleum products
e delivered to markets. In the United States, more than
million barrels of petroleum are transported daily. Pe-
oleum is carried chiefly by pipeline, tanker, barge, tank
uck, and railroad tank car.

Most petroleum moves through pipelines for at least
rt of its journey. Pipelines transport crude oil from
ells to storage tanks, to other carriers, or directly to re-
eries. Pipelines also carry petroleum products from
fineries to markets. Some of the largest pipelines can
rry more than a million barrels of oil daily. Pipelines
n be built in almost any kind of terrain and climate.
e Trans-Alaska Pipeline, for example, crosses 3 mountain ranges, more than 300 rivers and streams, and nearly 400 miles (640 kilometers) of frozen land. Pipelines cost much to build. But they are relatively cheap to operate and maintain and are generally the most efficient means of moving petroleum.

Tankers and barges transport oil on water. A tanker is a large oceangoing ship with compartments for liquid cargo. The largest tankers can hold more than a million barrels of petroleum. Tankers haul nearly all the oil imported by the United States. Barges, which can carry an average of 15,000 barrels of oil, are used mainly on rivers and canals.

Many petroleum products travel from refineries to markets by tank truck or railroad tank car. Tank trucks deliver gasoline to service stations and heating oil to houses. Such trucks can carry up to 300 barrels of fuel. Railroad tank cars range in capacity from about 100 to more than 1,500 barrels of oil. Some of these cars have equipment to keep petroleum products at a certain temperature or level of pressure.

Refining petroleum

From a distance, a petroleum refinery may appear to be a lifeless maze of towers, tanks, and pipes. But refin-

w oil is nsported

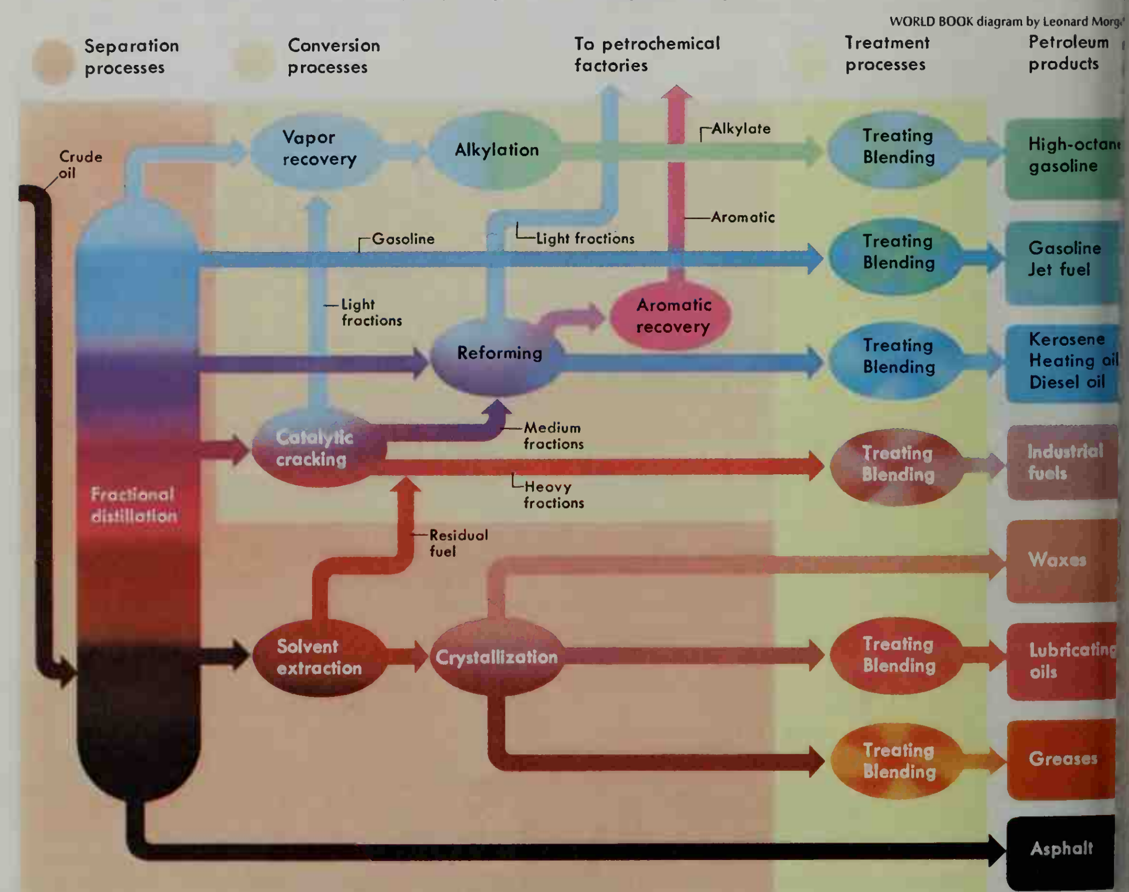
Petroleum is transported by a variety of methods during its journey from oil field to consumer. Nearly all oil moves through pipelines for at least part of the route. After crude oil is separated from natural gas, pipelines transport the oil to another carrier or directly to a refinery. Petroleum products travel from the refinery to market by tanker, truck, railroad tank car, or pipeline.

WORLD BOOK illustration by Robert Keys

eries hum with activity day and night. They can operate continuously for up to five years before being shut down for repairs. Refineries range in size from small plants that process about 150 barrels of crude oil a day to giant complexes with a daily capacity of more than 600,000 barrels.

The basic job of a refinery is to convert petroleum into useful products. Crude oil consists chiefly of combinations of hydrocarbons, as described in the section of this article called *The uses of petroleum.* Refineries separate the oil into various hydrocarbon groups, or fractions. The fractions are then chemically changed and treated with other substances. These refining processes may be classified as (1) separation, (2) conversion, and (3) chemical treatment.

Separation. The first stage in petroleum refining is *fractional distillation,* which is a process that separates crude oil into some of its fractions. Additional fractions may be separated from these fractions by the processes of *solvent extraction* and *crystallization.*



Fractional distillation is based on the principle that different fractions *vaporize* (boil) at different temperatures. For example, gasoline vaporizes at about 75° F. (24° C), but some of the heavy fuel oils have boiling points higher than 600° F. (316° C). As vapors, such fractions also *condense* (cool and become liquid) at different temperatures.

In fractional distillation, crude oil is pumped through pipes inside a furnace and heated to temperatures as high as 725° F. (385° C). The resulting mixture of hot gases and liquids then passes into a vertical steel cylinder called a *fractionating tower* or a *bubble tower.* As the vaporized fractions rise in the tower, they condense at different levels. Heavy fuel oils condense in the lower section of the tower. Such light fractions as gasoline and kerosene condense in the middle and upper sections. The liquids collect in trays and are drawn off by pipes along the sides of the tower.

Some fractions do not cool enough to condense. They pass out of the top of the fractionating tower into a *vapor recovery unit.* Other fractions, which vaporize at temperatures higher than those in the furnace, remain as liquids or semisolids. These *residues* are recovered from the bottom of the tower and refined into such

How oil is refined

Refineries convert crude oil into useful products in three basic stages. The first stage, called *separation,* consists of separating the oil into its various *fractions* (parts). The main process in this stage is *fractional distillation,* which separates light, medium, and heavy fractions. In *conversion,* the second stage, less useful fractions are converted into more valuable ones. The third stage is *treatment,* which improves the quality and performance of petroleum products.

ducts as asphalt and lubricating oils.

Fractions produced by distillation are called *straight-* *products.* Almost all of them must undergo conver- n and chemical treatment before they can be used.

Solvent extraction separates additional fractions from tain straight-run products. A chemical called a *sol-* *nt* either dissolves some of the fractions or causes m to separate out as solids. The principal solvents d include *benzene, furfural,* and *phenol.* Many refin- es improve the quality of kerosene and lubricating by solvent extraction.

Crystallization is used chiefly to remove wax and er semisolid substances from heavy fractions. The ctions are cooled to a temperature at which they form stals or solidify. They are then put through a filter that arates out the solid particles.

Conversion. Although nearly all petroleum can be ned into useful products, some fractions have much re value than others. Gasoline, for example, accounts almost half the petroleum products used in the ted States. But it makes up only about 10 per cent of straight-run products. On the other hand, some frac- ns that are in less demand than gasoline make up a her percentage of crude oil.

To increase the yield of desirable products from pe- leum, scientists have developed several methods to vert less useful fractions into those in greater de- nd. These methods fall into two main groups: (1) cking processes and (2) combining processes. Con- sion processes allow refiners to produce about half a rel of gasoline from each barrel of crude oil.

Cracking processes convert heavy fractions into ter ones, mainly gasoline. These processes not only rease the quantity of gasoline obtained from oil but improve the quality. Gasoline produced by cracking a higher *octane number* than the straight-run prod- Octane number is a measure of how smoothly fuel ns in an engine. See **Octane number.**

There are two principal types of cracking processes— *rmal cracking* and *catalytic cracking.* In thermal cking, heavy fractions are subjected to intense heat pressure in order to weaken the bonds that hold ge, complex molecules together. The heat and pres- e *crack* (break down) these molecules into the sim- r ones that make up light fractions.

n catalytic cracking, a *catalyst* is used to accelerate thermal cracking process. A catalyst is a substance t sets off or speeds up a chemical reaction without ng changed by the reaction. In this form of cracking, fractions are heated and then passed over minerals ed *zeolites,* certain types of clay, or other catalysts. combination of heat and catalytic action causes the vy fractions to crack into lighter ones. Catalytic cking is more widely used than thermal cracking be- se it requires less pressure and produces higher-oc- e gasoline.

During cracking, hydrogen may be added to the frac- s. This procedure, known as *hydrogenation,* further eases the yield of useful products.

Combining processes do the reverse of cracking. y combine or rearrange simple gaseous hydrocar- s to form more complex fractions. As a result, many he gases produced by distillation and cracking are verted into high-octane liquid fuels and valuable chemicals. The major combining processes include *polymerization, alkylation,* and *reforming.*

In polymerization, gases are subjected to heat and pressure in the presence of a catalyst. The hydrocarbon molecules unite and form larger molecules known as *polymers.* Polymers are essential ingredients in high-octane gasoline. Alkylation is similar to polymerization. It produces a fraction called *alkylate,* which is used in both aviation fuel and gasoline. In reforming, the molecules in gases form different hydrocarbon groups after exposure to heat and a catalyst. Reforming produces high-octane fuels and *aromatics,* which are chemicals used in making explosives, synthetic rubber, food preservatives, and many other products.

Chemical treatment. Nearly all fractions are chemically treated before they are sent to consumers. The method of treatment depends on the type of crude oil and on the intended use of the petroleum product.

Many fractions are treated to remove impurities. The most common impurities are sulfur compounds, which can damage machinery and pollute the air when burned. Treatment with hydrogen is a widely used method of removing sulfur compounds. In this method, fractions are mixed with hydrogen, heated, and then exposed to a catalyst. The sulfur in the fractions combines with the hydrogen, forming hydrogen sulfide. The hydrogen sulfide is later removed by a solvent.

Some fractions perform better if they are blended or combined with other substances. For example, refineries blend various lubricating oils to obtain different degrees of *viscosity* (thickness). Gasoline is blended with chemicals called *additives,* which help it burn more smoothly and give it other special properties.

The petroleum industry

The petroleum industry is one of the world's largest industries. It has four major branches. The *production branch* explores for oil and brings it to the surface. The *transportation branch* sends crude oil to refineries and delivers the refined products to consumers. The *manufacturing branch* processes crude oil into useful products. The *marketing branch* sells and distributes the products to consumers. Gasoline service stations handle the largest share of these sales. Oil companies sell their petroleum products directly to factories, power plants, and transportation-related industries.

The petroleum industry plays a large role in the economy of many nations. In such developed countries as the United States and Canada, it provides jobs for a great many people. It also is a major buyer of iron, steel, motor vehicles, and many other products. In certain developing but oil-rich countries, petroleum exports furnish most of the national income. Petroleum is also a source of political power for such countries because many other nations depend on them for fuel.

In the United States, the petroleum industry ranks as one of the largest private employers. The industry includes about 45,000 companies, most of which are small firms that specialize in one branch of the industry. The larger companies are active in all branches. The eight largest oil firms handle about 50 per cent of the petroleum produced, refined, and sold in the United States. In addition to these companies, there are nearly 200,000 gasoline service stations, most of which are independ-

ently owned and operated. The petroleum industry employs about 1 $\frac{1}{2}$ million workers and has an investment of about $330 billion in plants and machinery.

The United States is one of the world's leading producers and refiners of petroleum. About 2 $\frac{1}{2}$ billion barrels of crude oil are produced by U.S. wells annually. Only Saudi Arabia produces more petroleum. About 5 $\frac{1}{2}$ billion barrels of petroleum annually, or about a fourth of the world total, are processed by U.S. refineries. The United States is also the world's largest consumer of petroleum. The nation's demand for crude oil far exceeds domestic production. As a result, the country imports more than 60 percent of the oil it uses.

The price of imported crude oil has risen since the early 1970's, leading the U.S. petroleum industry to look for new ways to increase domestic oil production. The industry is researching methods of oil production in extremely harsh environments, such as the Arctic and underwater depths greater than 6,500 feet (2,000 meters). Researchers are also seeking more efficient techniques for recovering petroleum and for converting coal, oil shale, bituminous sands, and other plentiful hydrocarbons into synthetic oil and gas. In addition, researchers are studying such alternative sources of energy as the sun, wind, and internal heat of the earth.

In Canada, the petroleum industry is owned and run largely by private companies. In 1975, a government corporation called Petro-Canada became involved in exploring for new reserves and in developing synthetic forms of oil. Legislation passed in 1991, however, allows Petro-Canada to sell stock, changing its status to that of a publicly held corporation. The government also participates in the petroleum industry through its power to grant mineral leases to oil companies.

The petroleum industry in Canada began to expand rapidly in 1947, when prospectors made a great oil strike in Leduc, Alberta. Annual production jumped from about 8 million barrels of oil in that year to a peak of about 650 million barrels in the mid-1970's. Canada was a leading exporter of oil to the United States until 1975. Since then, Canada's reserves and production have declined, and it has reduced oil exports to the United States. Canada produces about 800 million barrels of oil annually. The nation's refineries process more than 600 million barrels annually, which makes Canada one of the world's leading refiners.

More than 1,500 Canadian companies produce petroleum. However, the 20 largest firms account for about 80 percent of Canada's oil production. More than 60,000 people work in the production and manufacturing branches of the oil industry, and many others have jobs in the transportation and marketing branches.

In other countries. During the early 1900's, foreign oil companies began to develop the petroleum industry in various countries in the Middle East, Africa, and other parts of the world. These firms, most of which were American or European, received ownership of the oil they discovered and produced. In return, they paid the host countries taxes and a share of the income from oil sales. Beginning in the 1950's, however, more and more host countries came to feel that they were not receiving a large enough share of the oil income. Today, many of these countries have acquired part or total control of the oil industry within their borders, either by negotiating with the foreign firms or by taking them over. A number of the countries belong to the powerful Organization of Petroleum Exporting Countries (OPEC).

OPEC, which was formed in 1960, consists of a group of nations that depend heavily on oil exports for their income. These nations include Libya, Nigeria, Venezuela, and the major oil-producing countries of the Middle East. OPEC members provide about 45 percent of all oil exports. Thus, the amount they produce and the prices they agree to charge largely determine the cost of petroleum. Industrialized countries are so dependent on imported oil that OPEC can use oil as an economic and political weapon. In the 1970's, OPEC raised oil prices so drastically that its members were able to increase their income from oil while restricting production.

Petroleum conservation

The world's supply of oil is limited and will eventually run out. Some experts predict that if oil consumption continues to rise, existing petroleum reserves will be exhausted by the early 2000's. Conservation of oil has thus become urgent for all nations, but particularly for those

at use the most energy. It is estimated that the United ates, which consumes about 25 per cent of the oil pro- ıced in the world, could reduce its energy needs by ılf through an active program of conservation.

There are almost as many ways to conserve petro- um as there are to use its products. The oil industry ıs adopted measures to maximize production and re- ıce waste at oil fields and refineries. Some measures ıve become law in the United States, Canada, and her countries. For consumers, conservation includes ıveling less by car, lowering furnace thermostat set- ıgs in winter, and raising air-conditioning thermostat ttings in summer. Consumer conservation measures ve become law in numerous nations.

Conservation by the oil industry. Most of the oil- oducing states in the United States and most such ovinces in Canada have commissions that regulate oil mpanies. One function of these regulatory commis- ons is to ensure that oil companies recover petroleum ficiently. A commission may therefore restrict the mber of wells drilled in an area and the rate at which ells are made to produce. Without such restrictions, e natural drives in oil fields would soon be exhausted, d much oil might be wasted.

The oil industry itself has developed a number of ethods of conservation. Most of them are classed as (1) -field conservation or (2) refinery conservation.

Oil-field conservation consists chiefly of methods to crease the amount of petroleum recovered. One of the ost widely used measures of oil-field conservation is a oling system called *unitization*. Under this system, o or more oil companies working in the same field ree to operate as a unit. Unitization enables the com- nies to make the most efficient use of natural and arti- ial energy in recovering oil.

Refinery conservation is aimed mainly at reducing e amount of heat energy used in refining. Most refin- es have devices called *heat exchangers,* which recy- e excess heat from such processes as fractional distil- ion and thermal cracking. New catalysts are being veloped to lower the energy requirements of the emical reactions. Many plants use computers to main- n furnaces and heaters at the most efficient tempera- es. Heat energy is also conserved by insulating pipes, ks, and other refinery equipment.

Conservation by consumers. Some of the most ex- sive conservation programs have been adopted by mmercial consumers of petroleum. Many manufactur- have installed equipment to store energy and re- ce fuel consumption in their plants. Such materials as minum and paper are reused in some factories be- se recycling waste products requires less energy n manufacturing new products.

Certain conservation measures originally adopted by ne businesses and factories are now legally enforced. he United States, for example, temperatures in most rk areas cannot be cooled below 78° F. (26° C) in sum- r nor heated above 65° F. (18° C) in winter. American l Canadian automobile manufacturers are required law to produce fuel-efficient cars.

n the home, common sense is often the best guide to ing energy. In cold months, for example, people can e advantage of solar energy simply by opening their tains during the day. They can further reduce fuel consumption by closing the curtains at night and by turning off the heat in rooms that are not being used. Homeowners who live in cold climates can conserve heat by installing storm windows, weather stripping, and other forms of insulation.

Most consumers can also conserve on fuel that they use outside the home. By keeping automobiles well tuned and by driving within speed limits, motorists can minimize gasoline consumption. They can save even more fuel by purchasing fuel-efficient cars, forming car pools, or switching to public transportation.

History of the use of petroleum

People have used petroleum for thousands of years. The Bible mentions that Noah used a solid form of petroleum called *pitch* in building the Ark. The ancient Egyptians coated mummies with pitch. About 600 B.C., King Nebuchadnezzar II used pitch to build the walls and pave the streets of Babylon.

In America, the Indians used crude oil for fuel and medicine hundreds of years before the first white settlers arrived. In the early 1600's, missionaries traveling through what is now Pennsylvania found Indians scooping up oil from surface pools. The remains of wells in the Eastern United States indicate that the Indians also obtained oil from underground deposits.

By 1750, the American colonists had found many oil seepages in New York, Pennsylvania, and what is now West Virginia. Some wells that were dug for salt produced oil. Salt makers regarded the oil as a nuisance, but other people found uses for it. About 1857, Samuel M. Kier, a Pittsburgh pharmacist, promoted oil as a cure for many ailments. The frontiersman Kit Carson sold oil as axle grease to pioneers.

A major breakthrough in the use of petroleum occurred in the 1840's, when a Canadian geologist named Abraham Gesner discovered kerosene. This fuel could be distilled from coal or oil. Kerosene became widely used for lighting lamps, and oil quickly rose in value.

Beginnings of the oil industry. Most historians trace the start of the oil industry on a large scale to 1859. That year, a retired railroad conductor named Edwin L. Drake drilled a well near Titusville, Pa. Drake used an old steam engine to power the drill. After Drake's well began to produce oil, other prospectors drilled wells nearby. Within three years, so much oil was being produced in the area that the price of a barrel dropped from $20 to 10 cents.

By the early 1860's, the oil boom had transformed western Pennsylvania. Forests of wooden derricks covered the hills, and thousands of prospectors crowded into the new boom towns. At first, wagons and river barges carried the oil to refineries on the Atlantic Coast. But the growing volume of oil soon required more efficient means of transportation. Railroads established branch lines to the fields and began to haul oil. In 1865, the first successful oil pipeline was built from an oil field near Titusville to a railroad station 5 miles (8 kilometers) away. Within 10 years, a 60-mile (97-kilometer) line ran from the oil region to Pittsburgh.

Prospectors discovered that other states had even larger oil deposits than Pennsylvania. By the 1880's, commercial production of oil had begun in Kentucky, Ohio, Illinois, and Indiana. In 1901, the opening of the Spindle-

top field in eastern Texas produced the first gusher in North America. During the 1890's and early 1900's, California and Oklahoma joined Texas as the leading oil-producing states. Annual U.S. oil production rose from 2,000 barrels in 1859 to 64 million barrels in 1900.

Commercial oil production spread rapidly throughout the world. Italy began to produce oil in 1860. After Italy, production began, in order, in Canada, Poland, Peru, Germany, Russia, Venezuela, India, Indonesia, Japan, Trinidad, Mexico, and Argentina. The first important oil discoveries in the Middle East occurred in Iran in 1908. Prospectors struck oil in Iraq in 1927 and in Saudi Arabia in 1938. Huge oil fields were later found in other states on the Persian Gulf.

Growth of the oil industry. During the 1800's, kerosene had been the chief product of the petroleum industry. Refiners considered gasoline a useless by-product and often dumped it into creeks and rivers. Then, about 1900, two events dramatically changed the situation—electric lights began to replace kerosene lamps, and the automobile rolled onto the American scene. The demand for kerosene thus declined just as an enormous market for gasoline opened up.

At that time, however, 100 barrels of crude oil produced only about 11 barrels of gasoline. As a result, petroleum refiners needed to increase the output of gasoline. The introduction of the thermal-cracking process in 1913 helped solve the problem. Within five years, refiners had more than doubled the amount of gasoline that they could produce from a barrel of crude oil.

American Petroleum Institute

The first gusher in North America blew in at the Spindletop field near Beaumont, Tex., in 1901. It sprayed more than 800,000 barrels of oil into the air until it was brought under control.

World War I (1914-1918) created a tremendous demand for petroleum fuels to power ships and airplanes. Fuels became as important as ammunition. After the war, the use of petroleum brought about big changes on farms. More and more farmers began to operate tractors and other equipment powered by oil. Agricultural productivity increased greatly as a result. In addition, gasoline taxes provided the money and asphalt furnished the raw material to build roads in rural areas. Farmers thereby gained better access to markets.

During World War II (1939-1945), the American oil industry proved its ability to increase production and develop specialized products quickly. Huge quantities of oil were produced and converted into fuels and lubricants. Such new refining processes as catalytic cracking and alkylation vastly increased the output of high-octane aviation gasoline. The United States supplied over 80 per cent of the aviation gasoline used by the Allies during the war. American refineries also manufactured *butadiene,* used in making synthetic rubber; *toluene,* an ingredient in TNT; medicinal oils to treat the wounded; and many other military necessities.

Postwar developments. The demand for petroleum products became even greater after World War II. The petroleum used in the United States climbed from abou $1\frac{3}{4}$ billion barrels in 1946 to almost $2\frac{1}{2}$ billion barrels in 1950. By the early 1950's, petroleum had replaced coal as the country's chief fuel. Some of the petroleum technology perfected during the war became the basis for peacetime industry. The petrochemical industry, for example, grew enormously as a result of the manufacture of synthetic rubber.

The United States was not alone in its rising level of petroleum consumption. Throughout the world, increased industrialization and rapid population growth created new and greater demands for oil. Control over the sources and transportation of oil soon became a vital issue in national and international politics.

In the United States, the issue of control over oil centered on the offshore deposits of Louisiana, Texas, and other states. These states claimed ownership of the *tide lands* (offshore areas within their traditional boundaries The federal government, however, insisted that the tide lands belonged to the nation. The dispute delayed the development of new offshore wells because oil companies did not know whether the states or the federal government owned the territory. Finally, in 1953, Congress passed an act that granted jurisdiction of the tidelands to the states and so enabled them to lease offshore sites to oil companies. In 1975, the Supreme Court limited the tidelands of most states to areas within 3 nautical miles (5.6 kilometers) of their coastline.

On the international scene, the struggle for oil focused on the Middle East, which has more than half of the world's petroleum reserves. The petroleum industry in many Middle Eastern countries was owned or operated by American or European companies. In 1951, Iran became the first country to take over the holdings of such firms. By the mid-1970's, most nations in the Middle East either fully controlled or held a majority interest in their petroleum industry.

Recent developments. The ever-increasing use of petroleum products, especially in developed countries,

ias helped raise the living standards of many people. 3ut it has also resulted in some serious problems, which nclude (1) the energy shortage, (2) the fluctuating price of oil, and (3) environmental pollution. It may also contribute to a process known as *global warming.*

The energy shortage. During the 1960's, prospectors liscovered significant amounts of oil in northern Alaska nd in the North Sea. But these gains were offset by rising levels of consumption in many industrialized naions, including Japan, the United States, and Western uropean countries. During the late 1960's and early 970's, political instability in the Middle East disrupted he flow of oil to Japan and some Western nations. In the 970's, the member countries of OPEC, who held the najority of the world's remaining oil reserves, realized hey could control the price of oil if they acted in unison. \s a result, OPEC increased the price of oil. The price of barrel of crude oil jumped from about $2.75 in 1973 to peak of $34 in 1981.

Due to the increasing price, many countries began nergy-conservation programs. In addition, oil and gas xploration increased throughout the world. In the Unitd States, companies redrilled many wells that had been onsidered insufficiently productive or not profitable nough. Consequently, the price dropped back to 12.50 in 1984. Since then, the price has fluctuated beween about $10 and $35 per barrel.

The fluctuating price of oil. Many economists agree hat it is difficult to predict future oil prices. When prices all, there is little incentive for consumers to conserve nergy or for companies to explore for new oil and gas eserves. Prices continue to drop until a shortage develps in the amount of oil that is immediately available for se. At this point, prices rise and exploration intensifies. lowever, it can often take as long as 10 years from the rst day of exploration for oil production to begin, espeially in offshore wells. During the waiting period, little r no new production occurs, and so the shortage eepens and prices continue to increase.

Environmental pollution. The production, transportaon, and use of petroleum have created problems of enironmental pollution. Tankers and offshore drilling acidents can cause oil spills that pollute the water, lamage beaches, and destroy wildlife.

The burning of *fossil fuels* (coal, oil, and gas) by motor ehicles, power plants, and factories is the chief source f air pollution in most cities. Many laws have been assed throughout the world to control pollution. The etroleum industry has invested heavily in the developnent of techniques and products to minimize pollution. o reduce the pollutants in automobile exhaust, for exmple, oil companies cooperated with car manufacturrs in the production of unleaded gasoline. But rising vels of oil consumption have offset some of the gains gainst pollution.

Global warming is an increase in the average temperure of the earth's surface. Since the late 1800's, the avrage temperature has increased about 0.5 to 1.5 ahrenheit degrees (0.3 to 0.8 Celsius degree). The burnig of fossil fuels may contribute to global warming by dding carbon dioxide gas to the earth's atmosphere. ossil fuels produce this gas when they burn. The added irbon dioxide would contribute to global warming by nhancing the *greenhouse effect.* This effect warms the earth's lower atmosphere and surface through a complex process involving sunlight and atmospheric gases and particles.

The future of the petroleum industry. Most experts predict that the worldwide demand for petroleum will continue to increase in the years ahead. They also predict that the world's dependence on oil from the Middle East will increase. In addition, most experts believe that oil will become scarce sometime in the mid-2000's unless large new deposits are found or alternate energy sources are discovered.

The only long-range solution to the energy problem is the introduction of alternative sources of energy. Scientists have developed techniques to convert coal into oil and gas, and to produce oil from bituminous sands and oil shale. However, these processes are expensive, and many of them have environmental problems of their own. But if oil prices continue to increase, alternative sources eventually may be able to compete in cost with petroleum.

It will probably be many years before alternative fuel sources make a major contribution to the world's energy supply. Until then, oil companies and oil consumers will need to conserve existing reserves by using energy as efficiently and sparingly as possible.

Career opportunities

The petroleum industry employs many kinds of workers, from unskilled laborers to highly trained scientists and engineers. Information on careers in the industry can be obtained from the American Petroleum Institute in Washington, D.C.

Scientists and engineers play a vital role in the petroleum industry. Geologists and geophysicists explore for oil. Other scientists, such as biologists and ecologists, study the environmental effects of the industry's operations. Petroleum engineers supervise well drilling and oil recovery. Oil companies also employ chemical, civil, electrical, and mechanical engineers. All these jobs require college training.

Oil-field workers include derrick workers, drillers, roughnecks, and *roustabouts* (production workers). These workers must have good physical coordination as well as mechanical ability.

Machinists and maintenance workers include mechanics, welders, and electricians. Such jobs require good mechanical judgment and the ability to do precision work.

Control workers and equipment operators keep petroleum flowing efficiently through the various stages of production and refining. These workers read and maintain gauges, meters, and other instruments in oil fields, in refineries, and along pipelines. In addition, these workers check all equipment to see that it runs properly. As computers take over many of these operations, oil companies are hiring increasing numbers of computer maintenance specialists who must have special training.

Marketing workers sell petroleum products and services. They include service station attendants, people who sell petrochemicals to manufacturers, and *jobbers* (individuals who buy from producers and sell to retail dealers). Marketing jobs require business judgment and personal qualities to attract and retain customers.

Clerical and administrative workers handle the business operations of the petroleum industry. Clerical jobs may require training in such subjects as bookkeeping and the operation of office machines. Most administrative jobs require college training in engineering, geology, or geophysics. Robert C. Laudon

Petroleum coke is a useful product obtained in refining crude oil. The production of petroleum coke begins after all the gasoline, kerosene, gas oils, lubricating oils, and other products have been distilled from crude oil. Pumps then force the heavy *residual oil* that remains through tubes of a furnace. There, the oil is heated to a high temperature. The heated oil stews in *coking drums* until it becomes solid coke. The coke is then treated to remove impurities, especially sulfur. Petroleum coke has many uses in industry. For example, it is used in making carbon or graphite electrodes for flashlight batteries and dry cells. Coke is also important in the refining of various metals and in the production of abrasives and heat-resisting materials. It is used in producing synthetic graphite for nuclear reactors. Carbon made from coke is used in the chemical industry for its resistance to chemicals. W. Simon Tortike

Petrology, *pih TRAHL uh jee,* is a branch of geology that deals with the origin and composition of rocks. Petrologists analyze the physical and chemical conditions involved in the formation of the three major types of rocks: *igneous, metamorphic,* and *sedimentary* (see **Rock**). Such analysis helps provide clues to the origin and development of the earth.

Petrologists work both in the field and in the laboratory. They study the location, position, and distribution of rocks in nature. They use microscopic and chemical techniques to determine the minerals that make up individual rocks. In addition, petrologists attempt to reproduce in a laboratory the temperature and pressure that affect rock formations. These experiments provide data about the physical and chemical properties of rocks under varying conditions. Maria Luisa Crawford

Petronas Towers, in Kuala Lumpur, Malaysia, are the tallest buildings in the world. Spires atop the 88-story towers bring their structural height to 1,483 feet (452 meters). A double-decker bridge joins the two buildings at the 41st and 42nd stories. The towers are the headquarters of Petronas, also known as Petroliam Nasional

erhad, Malaysia's national oil and gas company.

The Petronas Towers are designed to reflect Islamic rchitecture. The towers are constructed primarily of eel, concrete, and glass. The floor space of the two uildings totals about 4,600,000 square feet (427,000 quare meters).

The Petronas Towers were built by two international roups of construction and engineering firms. Construc-on began in 1993 and was completed in 1998. The ructures were designed by Cesar Pelli & Associates, an rchitectural firm in the United States.

etronius, *pih TROH nee uhs* (?-A.D. 66), wrote the rst Roman novel, the *Satyricon*. Only sections of the ovel exist today. The work traces the adventures of iree Romans traveling in Italy. Through a mixture of rose and poetry, Petronius portrayed conditions of real e under the Roman emperor Nero. He described a so-ety filled with dishonesty, insincerity, and vice. Nearly ne-third of the surviving novel deals with a rich but un-ducated man called Trimalchio and a lavish dinner par- that he gave. During the dinner, Trimalchio attempts impress his guests with what he thinks is good taste. owever, the host's showiness and vulgarity expose his iltural inferiority to his intellectually superior guests. A umber of scholars believe that Petronius wrote the ovel to ridicule Roman society under Nero.

etty, Richard (1937-), became one of the great-st and most popular drivers in American automobile cing history. Petty specialized in driving stock cars—dinary sedans whose engine and structure have been tered to provide more power and speed. Petty holds most every record of the National Association for ock Car Auto Racing (NASCAR). He started more races 185) and won more races (200) than any other stock r driver. He won the Winston Cup NASCAR national cing championship seven times, a record he holds ith Dale Earnhardt. Petty retired as a driver in 1992.

Petty was born outside Level Cross, North Carolina, ear Randleman. He began to compete in NASCAR ces in 1958. He was nicknamed "King Richard" because his achievements and his popularity. His father, Lee tty, was a noted pioneer stock car racer.

etunia, *puh TOO nee uh,* is the name of a group of ants known for their beautiful, funnel-shaped flowers. tunias rank as one of the most popular garden flowers the United States and many other countries.

A petunia's flowers grow 4 inches (10 centimeters) or ore across. They may be pink, rose, salmon, red, hite, blue, or a mixture of colors. Some varieties have a igle set of petals. Others have a double set.

There are about 30 *species* (kinds) of petunias. Tiny irs cover the stems and leaves of most cultivated petu-as, but some wild species have almost no hairs. Most tunias are *perennials*—that is, they live at least three ars. However, gardeners usually raise the plants as *an-als* (flowers that live one year or less) because they wer during their first year. People may grow petunias m cuttings or from seeds.

Gardeners normally grow petunias in prepared ound beds or in window boxes. Some plant the flowers in hanging baskets. The plants thrive in sunny locations. Their flowers bloom in summer and early fall.

Petunias originated in Argentina, Bolivia, Brazil, Paraguay, and Uruguay. Europeans first brought them from South America to Europe in the 1820's. Gardeners in Europe developed the first cultivated petunias later in the 1800's. Roy E. Gereau

Scientific classification. Petunias belong to the nightshade family, Solanaceae. They make up the genus *Petunia*. The scientific name for cultivated petunias is *P. hybrida*.

Pevsner painted until 1923, when he turned to sculpture, perhaps because of the influence of his brother. One of Pevsner's best-known early sculptures is a 1926 portrait of artist Marcel Duchamp made of blades of metal and transparent plastic. In his later work, Pevsner formed bronze, brass, and copper constructions with deep hollows that unite light and space.

Pevsner was born in Orel, Russia. He settled permanently in Paris in 1923. Joseph F. Lamb

Pewee is the name of 11 species of small birds that are native to the Western Hemisphere. They belong to a family of birds called *flycatchers* (see **Flycatcher**). Pewees are about 6 to 8 inches (15 to 20 centimeters) long. They have gray-brown to greenish-gray backs and pale gray breasts. Most pewees have two white bars on their wings.

Pewees range from southern Alaska and southern and eastern Canada to Argentina. The best-known species in the United States are the *western wood-pewee,* also called the *western pewee,* and the eastern *wood-pewee,* also known as the *eastern pewee.* The western wood-pewee lives in woodlands from southern Alaska and western Canada to Central America. The eastern wood-pewee inhabits forests from southeastern Canada to Florida and Texas. The name *pewee* comes from the eastern wood-pewee's call, which sounds like *pee-a-wee.* Both species breed in the United States and Canada and migrate to Central and South America for the winter. They return to their nesting grounds in April or May. The birds sing at the first sign of daybreak and throughout the day into early evening.

WORLD BOOK illustration by Trevor Boyer, Linden Artists Ltd.

The eastern wood-pewee sings throughout the day.

Eastern and western wood-pewees build nests out of plant fibers. They cover the outside of the nest with lichens or leaves to camouflage it. Female pewees lay two to four eggs that are white with brown speckles on the larger end. The eggs hatch in about 12 days. Pewees eat chiefly ants, flies, bees, and beetles.

Fred J. Alsop III

Scientific classification. Pewees belong to the flycatcher family, Tyrannidae. The scientific name for the western wood-pewee is *Contopus sordidulus.* The eastern wood-pewee is *C. virens.*

Pewter, *PYOO tuhr,* is an alloy that consists mainly of tin. It also contains antimony and copper. Pewter has a metallic, white color much like that of silver and a finish that can vary from dull to highly polished. It is widely used in making such articles as bowls, candlesticks, and tea services. Pewter is a soft alloy and dents easily. Articles made of pewter require care in handling.

Pewter consists of at least 90 percent tin, a very soft metal. From 2 to 8 percent antimony and up to 3 percent copper are added to harden and strengthen pewter. At one time, most pewter also contained lead. But lead caused tarnishing. It also could dissolve in some foods and beverages served in pewterware, forming toxic substances. During the mid-1700's, a nonlead pe-ter called *Britannia metal* came into use in England. It consisted of tin, antimony, and copper and did not ta nish. Today, Britannia metal and pewter are both use make pewter articles.

WORLD BOOK photo by Ralph B

Pewter is an alloy that has a white, metallic color resembling ver. Pewter is used to make bowls and tea services.

How pewter is made. The first step in making pe ter is to melt the tin in a pot called a *crucible.* Next, an mony and copper are dissolved in the liquid tin. Once mixed thoroughly, the alloy is poured into metal, plas or wooden forms to cast the desired articles.

Pewter can also be poured into iron molds and the rolled and cut into standard shapes. Such shapes include disks, rectangular sheets, and wires, which craf workers form into various objects. Pewter disks are shaped by a process called *spinning.* Spinning consis of holding the disk against a steel or wooden form turned by a machine called a *lathe.* Craftworkers use blunt tools to push the pewter into the shape of the spinning form.

Pewter sheets can be shaped into various items by hammering the metal with a leather, metal, plastic, or wooden mallet. Craftworkers use pewter wires as de rative trim for pewter articles. The parts of many pew items are joined by a process called *soldering* (see **S der**).

Caring for pewter. Pewter, if given proper care, does not tarnish or require polishing. It should be washed in hot, soapy water as soon as possible after ing used. Pewter should be rinsed in clear hot water dried immediately with a soft cloth. Pewter articles should not be left to dry in the air. Air drying sometim leaves water spots, which are difficult to remove. Pew should never be washed in a dishwasher because the heat of the drying cycle can darken the surface.

Pewter serving pieces should not be used in prepa ing food. Pewter has a melting point between 471 °F (244 °C) and 563 °F (295 °C), and so it can melt if placed an oven or on a burner.

History. Pewter ranks as one of the oldest known al-oys and may have been used as early as 1500 B.C. From he A.D. 1300's to the 1800's, people in England and the est of Europe used pewter household utensils exten-sively. Pewter became popular with people who could not afford gold and silver serving pieces.

Most of the early pewter used by the American colo-nists was imported from England. In 1635, an English-nan named Richard Graves opened the first pewter shop in the American Colonies. His shop was in Salem n the Massachusetts Bay Colony. The colonists used nany pewter articles, but few such items made by colo-nial craftworkers still exist. Tin had to be imported from England, and the English placed a high tax on it. Thus, he colonists had their old or damaged pewterware nelted and recast into new objects. In the mid-1800's, china and glassware gradually replaced pewter.

Today, most antique pewter is in museums or private collections. Such pewter may contain lead, and so it should not be used for serving food. Making objects out of pewter is a popular craft. Paul E. Davis

Pfiesteria, *fees TEER ee uh,* species are harmful aquat-ic organisms found in coastal regions of the eastern United States. They are a kind of *dinoflagellate,* a group of single-celled organisms that swim by means of two hairlike structures called *flagella. Pfiesteria* exists in as many as 24 different plant or animal-like forms. They usually live buried in sediment in a harmless form called a *cyst.* They can also change into a harmful mobile form.

Pfiesteria changes into a mobile form when fish swim nearby. The tiny organisms then excrete powerful *toxins* (poisons) into the water. The toxins weaken the fish, making them swim slowly and allowing disease-causing bacteria and fungi to eat away at their skin. Eventually, the toxins paralyze and kill the fish. Entire schools of fish can be killed by swimming into waters where *Pfiesteria* is active. Dead and dying fish float on the surface, often covered with large bloody sores, following such an at-tack. *Pfiesteria* feeds on the dead fish.

Human beings and other animals can be harmed by exposure to water that contains *Pfiesteria* toxins. People exposed to the toxins can suffer skin sores, nausea, res-piratory problems, fatigue, and temporary memory loss.

Pfiesteria was first discovered in 1991 after millions of fish were found killed in waters off North Carolina. Sci-entists think that pollution, especially fertilizer runoff, sewage, and animal wastes from farms near coastal wa-ters, has caused more frequent *Pfiesteria* outbreaks.

JoAnn M. Burkholder

Scientific classification. *Pfiesteria* are in the kingdom Pro-tista. Two species are *Pfiesteria piscicida* and *P. shumwayae.*

pH is a number used by scientists to indicate the con-centration of hydrogen ions in a solution. pH generally ranges from 0 to 14. The letters *pH* stand for *potential hydrogen.* At 77 °F (25 °C), a pH below 7 indicates that a solution is acidic, and a pH above 7 indicates that a solu-tion is *basic* (alkaline). A *neutral* solution, such as pure water, is neither acidic nor basic and has a pH of 7. Hu-man blood has a pH of about 7.4.

The Danish biochemist Søren Sørensen invented the pH system in 1909. A solution's pH is defined as the neg-ative logarithm, to the base 10, of its hydrogen-ion con-centration. This concentration is expressed in *moles* of hydrogen ions per liter of solution (see **Mole**). A solu-tion with a pH of 6 contains 10^{-6} (one millionth) of a mole of hydrogen ions per liter.

pH is often measured with an electronic *pH meter* or with special dyes called *acid-base indicators.* The color of an indicator depends on the concentration of hydro-gen ions. *pH paper* contains several indicators that change color at different pH's. When dipped into a solu-tion, the paper's color indicates the approximate pH of the solution. pH is used to analyze body secretions, to test soil suitability for certain crops, and for various in-dustrial purposes. Phaëthon, *FAY uh thahn,* in Greek mythology, was the son of the sun god Helios and the sea goddess Clym-ene. To learn whether Helios was truly his father, Phaë-thon journeyed to the palace of the sun god in the east. There Helios, to reassure Phaëthon, promised to grant his son any favor. Phaëthon rashly asked to drive the sun chariot through the sky for one day. Helios reluctantly consented, but Phaëthon, being a mere mortal, was un-able to control the fiery divine steeds. They flew so high that the earth froze and a scar—the Milky Way—was carved on the sky. The steeds then flew so low that peo-ple were scorched black, streams dried up, and rocks split. Zeus, the king of the gods, rescued the world from destruction by striking Phaëthon with a thunderbolt. Phaëthon fell into a river and perished.

Phalarope, *FAL uh rohp,* is a small sandpiperlike bird that breeds in the Northern Hemisphere and winters in the Southern Hemisphere. The *red phalarope* and the *red-necked,* or *northern, phalarope* breed in the Arctic and subarctic. They winter on the high seas of the At-lantic and Pacific oceans.

The phalarope female is larger and more brightly col-ored than the male phalarope. The female does the courting and establishes the nesting territory. The male builds the nest and incubates the eggs. However, both the male and the female care for the young.

George L. Hunt, Jr.

Scientific classification. Phalaropes make up the phalarope family, Phalaropodidae. The scientific name for the red phala-rope is *Phalaropus fulicaria.* The red-necked phalarope is *P. loba-tus.*

Pharaoh, *FAIR oh,* was a title of the later kings of an-cient Egypt. The Egyptians did not call their ruler pharaoh until the Eighteenth Dynasty (1554-1304 B.C.). Even then, pharaoh was not one of the king's most im-portant titles. Writers of books in the Old Testament used the word *pharaoh* as a title for the king of Egypt.

The word *pharaoh* comes from two Egyptian words that mean *great house.* At first, these words described the royal palace, not the king.

Egyptians considered the pharaoh a god and the son of a god. They thought he was the sky god Horus in hu-man form, and the son of Re, the sun god. In theory, the pharaoh owned all the land and ruled the people. In re-ality, his power was sometimes limited by strong groups, including the priests and nobles. The pharaoh's actions were governed by rules of conduct that the Egyptians believed the gods had set down.

Pharaoh Hound Club of America

The pharaoh hound is a sleek, swift-running dog.

Pharaoh hound is one of the oldest breeds of dogs. Pharaoh hounds originated in ancient Egypt, where they were used for hunting antelope and other game. Their likenesses have been found on walls of the tomb of Pharaoh Antefa II, dating to 2300 B.C. About 1500 B.C., the Phoenicians brought the breed to the island of Malta, where it survived into modern times. The breed was introduced into the United States in the 1950's.

Pharaoh hounds are sleek dogs that stand from 21 to 25 inches (53 to 64 centimeters) high at the shoulder and weigh from 35 to 50 pounds (16 to 23 kilograms). Their short, flat, glossy coat is a rich tan. Pharaoh hounds have white toes and a starlike white marking on the chest. The tip of their whiplike tail is also white, and many of the dogs have a white line up the center of the face. Pharaoh hounds "blush" when excited—that is, their nose and their erect ears change from the normal flesh color to a deep rose. Their eyes are an unusual amber color. Pharaoh hounds hunt by both sight and scent. They move swiftly and gracefully, and their bite is powerful.

Pharisees, *FAR uh sees,* were members of an ancient Jewish group that became an important political party in Palestine during the reign of Queen Alexandra (76-67 B.C.). The political role of the Pharisees ended under the reign of Herod the Great (37-4 B.C.).

The Pharisees developed a philosophy that attributed an important role to fate and to God. They believed that even though people have free will, fate or God will also play a role in people's actions. The Pharisees also believed that a person's soul is either rewarded or punished after death.

In the Gospels, the Pharisees were not politicians or philosophers, but Jews who stressed the laws of dietary purity. According to the Gospels, the Pharisees ate only with other "pure" Jews, while Jesus and His disciples ate with people who did not keep the law. Also, the Pharisees stressed the washing of hands, while the early Christians ignored this practice. Similarly, the Pharisees fasted, but Jesus and His disciples did not.

The Gospels often portrayed the Pharisees as the main Jewish opponents of Jesus, who easily overcame their opposition. In Matthew, Saint John the Baptist called them "a brood of vipers," and in Luke, Jesus described them as hypocrites. These insults were directed at the Pharisees to contrast the ethical laws of Jesus with the purity laws and rituals of the group.

The Pharisees were often in conflict with another Jewish group called the Sadducees. Most of their disagreements revolved around issues of purity. The Pharisees believed that the purity laws should be kept by all Jews and were not limited to the priests and the area around the Temple in Jerusalem. The Pharisees believed that all Jews should eat as if they were priests presiding at the altar of the Temple. Gary G. Porton

Pharmacology, *FAHR muh KAHL uh jee,* is the scientific study of the effects chemicals have on living things. The scientists who study such chemical effects are known as *pharmacologists.* Pharmacologists consider all chemicals that affect living things to be drugs. Much of their study deals with how drugs modify tissue and organ functions. Pharmacology differs from *pharmacy,* which is a profession concerned mainly with the preparation and distribution of drugs for public use.

Pharmacology is divided into several fields. *Pharmacodynamics* studies the effects of drugs on living organisms. *Pharmacokinetics* deals with how the body takes up, distributes, and eliminates drugs. *Toxicology* deals with poisons and their effects, detection, and treatment. *Clinical pharmacology* examines the usefulness and poisonous qualities of drugs in the human body. Pharmacologists may work for universities, hospitals, government agencies, or pharmaceutical companies.

People have used plants and minerals to relieve or cure diseases since ancient times. Through the years, people have used such plants as the poppy, belladonna, and foxglove to treat certain conditions. The science of pharmacology began during the 1900's with the rise of chemistry. For the first time, scientists could analyze crude plant and mineral materials that acted on living tissues. By separating and studying the part of the plant or mineral that caused a reaction, scientists could then use the materials to make drugs. Barbara M. Bayer

Pharmacy is the profession concerned with the preparation, distribution, and use of drugs. Members of this profession are called *pharmacists* or *druggists.* They were once called *apothecaries.* The word *pharmacy* also refers to a place where drugs are prepared or sold. Most pharmacies, sometimes called drugstores, sell a variety of products in addition to drugs.

Duties of a pharmacist. Pharmacists fill prescriptions written by physicians or dentists and prepare labels for the medicines. On the labels, pharmacists include directions for patients given in prescriptions. At one time, pharmacists compounded their own medicines. Today, pharmaceutical manufacturers supply most drugs. But pharmacists must still compound some medicines and be able to prepare antiseptic solutions, ointments, and other common remedies. They also advise people on the selection of nonprescription drugs, such as cold tablets. In addition, pharmacists are responsible for the legal sale of narcotics and poisonous substances.

Training and careers in pharmacy. To become a pharmacist in the United States, a person must graduate from an accredited college of pharmacy. After finishing

his five- or six-year program, graduates must complete one year of internship under the supervision of a practicing pharmacist. Each state requires graduates to pass a state board examination before granting them a license to practice in the state. Canada has similar training requirements for pharmacists.

The United States has more than 70 accredited colleges of pharmacy, and Canada has 9. Most of these colleges are part of a large university. Pharmacy students must take courses in the biological sciences, chemistry, and mathematics, as well as in the humanities, to receive a bachelor's degree in pharmacy. They also must complete specialized professional courses. These courses include *pharmacology,* the study of the effects of drugs on living things; *pharmaceutics,* the physical chemistry of drugs; and *clinical pharmacy,* the application of the pharmaceutical sciences to patient care. A master's or doctor's degree is required for work in certain fields. Pharmacists may work in clinics, drugstores, hospitals, industrial plants, or research laboratories. They may also work for the military or government.

The American Pharmaceutical Association is the national organization of pharmacists in the United States. It was founded in 1852. The association seeks to maintain high standards of practice among its members. Information about career opportunities in pharmacy can be obtained by contacting the American Association of Colleges of Pharmacy in Alexandria, Virginia.

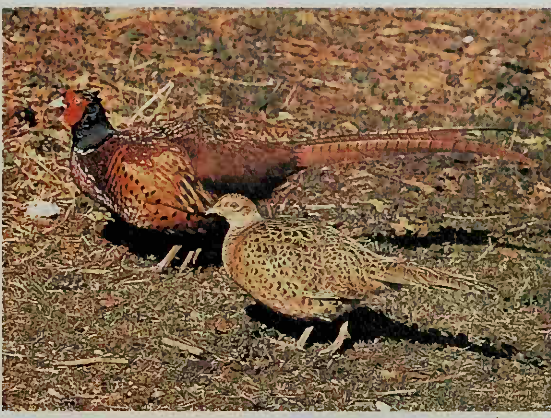
Pharynx, *FAR ihngks,* is a cone-shaped tube that connects the nose and mouth with the voice box and *esophagus* (tube leading to the stomach). The pharynx is about 5 inches (13 centimeters) long and has muscular walls lined with mucous membrane. It serves as a passageway for both air and food. In addition, the pharynx plays an important role in speech, especially in the production of vowel sounds.



When a person breathes in, air enters the pharynx from the nose or mouth. The air then passes through the *larynx* (voice box) and *trachea* (windpipe) into the lungs. This route is reversed when a person exhales.

Food enters the pharynx from the mouth. When a person swallows, a flap of cartilage called the *epiglottis* covers the opening of the larynx, and the vocal cords automatically clamp shut. These actions keep food from entering the trachea. Instead, it travels down the esophagus to the stomach. Barry L. Wenig

Pheasant, *FEHZ uhnt,* is the name of several species of medium-to-large birds closely related to peacocks and junglefowls. Pheasants are also related to the domestic chicken. Most pheasants are native to China and countries of Central and Southeast Asia. But some species have been brought to other parts of the world, where they have been released for hunting. People hunt pheasants for sport and for their tasty meat. Pheasants are also sought for their feathers.

Appearance and habits. Most pheasants have a long tail and a short, stout bill. Some have flaps of red skin on their heads forming *combs* or *wattles.* Males are called *cocks.* Nearly all cocks have beautiful patterns of brightly colored feathers. Females, called *hens,* have duller feathers of brown and tan with black markings.

Jane Burton, Bruce Coleman Ltd

Ring-necked pheasants are popular game birds. The male's head and neck have bright feathers. The female is drab-colored.

Kenneth W. Fink, Photo Researchers

Male golden pheasants have bright yellow heads and brilliant red breasts. Their colors make them attractive to females.

Most pheasants inhabit woodlands, but some species prefer cultivated fields. Other species of pheasants live in grasslands high in the Himalaya. Most pheasants do not undertake long migrations, but many make short seasonal journeys in search of food. Pheasants eat seeds, fruits, roots, greens, flowers, and insects and other small animals without backbones. Pheasants spend most of their time on the ground, although many species perch in trees at night. The birds can fly only for short distances but may reach speeds of 40 miles (64 kilometers) per hour.

In spring, pheasant cocks fight for possession of a mating area. They then attract hens by showing off their elegant feathers. The cocks accompany such elaborate displays with cackles, crows, screams, and whistles. The calls of the hens are limited mostly to clucks and peeps. A cock's territory usually includes several hens, with which he mates. Nearly all pheasants nest on the ground. The hen builds a nest of twigs and leaves in a secluded spot. But sometimes pheasants use a nest left in a tree. Hens lay from 2 to 15 eggs. Their eggs are plain or speckled and may be white, tan, or olive.

Kinds of pheasants. There are about 35 species of pheasants. One familiar species, the *ring-necked pheasant,* was found originally in central Asia. The Romans spread these birds to Europe about 2,000 years ago. Ring-necks were brought to North America in the 1800's, and they soon became a familiar game bird. Male ring

necks grow to a length of 30 to 36 inches (76 to 91 centimeters), including the tail. Their head and neck are covered with shiny greenish-blue feathers, and their body is brown, black, and white. Many cocks have a white band around their neck. Red skin encircles their eyes. The hens are mottled brown. They grow to a length of 21 to 25 inches (53 to 64 centimeters).

Another well-known species, the *golden pheasant,* adapts well to captivity and is a favorite in zoos. The male has a golden-yellow head and brilliant red breast. Golden pheasants come from the mountain forests of Tibet and central China, where they have become a rare species.

The large *Reeves pheasant* lives in small groups in the mountains of China. As part of its courtship dance, the cock ruffles its shimmering golden feathers and leaps repeatedly high into the air. During flight, it may use its long tail as a rudder or a brake. Bertin W. Anderson

Scientific classification. Pheasants belong to the family Phasianidae. The scientific name for the ring-necked pheasant is *Phasianus colchicus,* the golden pheasant is *Chrysolophus pictus,* and the Reeves pheasant is *Syrmaticus reevesi.*

Phenolic, *fih NOH lihk* or *fih NAHL ihk,* is any of a group of strong and inexpensive plastics materials. Phenolics are resistant to heat and to most solvents. They are excellent electrical insulators. Among the products made of phenolics are light switches, gears, and saucepan handles.

Phenolics are synthetic *polymers.* A polymer is a long, chainlike molecule. The "links" of the chains are repeating patterns of simple groups of atoms known as *monomers.* Phenolics are *thermosetting plastics*—that is, once the plastic has been formed, it cannot be reshaped by heat, pressure, or other physical means (see **Plastics** [Types of plastics]). Because of these properties, phenolics cannot be recycled.

Manufacturers use several different methods to produce phenolics. In the most common method, one of a group of organic compounds called *phenols* is mixed with formaldehyde in the presence of a *catalyst.* A catalyst is a substance that speeds up a chemical reaction without being used up by the reaction. The mixture is slowly heated, causing the molecules of formaldehyde to form chemical bridges between the *benzene rings* (ringlike structures of six carbon atoms) in the phenol molecules.

Manufacturers frequently add fillers or additives to phenolics to change their properties to suit various applications. Most phenolic products are shaped, using heat and pressure, in a process called *compression molding.* In addition, porous materials may be saturated with phenol and formaldehyde, allowing a phenolic to form within the structure of the material. This process is performed with wood to produce Formica-brand tabletops and other work surfaces. A similar process combines phenolic with certain mineral fibers or synthetic fibers to make brake linings for automobiles.

Phenolics are among the oldest plastics. The Belgian-born American chemist Leo Hendrik Baekeland developed the first phenolic in 1907. He patented it in 1909 as Bakelite. Stephen H. Carr

Phenology, *fih NAHL uh jee,* is the study of when certain biological events that depend on climate take place. Phenologists study how these events are affected by seasonal weather changes. The events include the migration of birds, the hibernation of animals, and the sprouting and flowering of plants. Farmers and others whose work is affected by weather can use the information to plan their activities. For example, in some areas alfalfa is ready to be cut about 30 days after the common lilac blooms. Farmers in these areas can predict when they will have to cut their alfalfa by observing when lilacs bloom.

Scientific organizations in the United States and other countries have formed networks of people who observe and report on certain phenological events. The organizations use the information to make *phenological maps.* Lines on the maps connect the places in which living things reach a certain stage at the same time.

Artificial satellites provide data on atmospheric temperatures, solar radiation, and the reflection of the earth's surface. This information helps scientists detect certain phenological events worldwide. For example, phenologists use this information to determine when vegetation will become green—or turn brown—in various regions. The data can be used to develop mathematical models of the life cycles of plants and animals raised in different climates. George B. Johnson

Phenolphthalein, *FEE nohl THAL een* (chemical formula, $C_{20}H_{14}O_4$), is a chemical compound used as an indicator of alkalinity or acidity, and as a laxative. It is also used in making dyes.

Phenolphthalein is prepared by heating phenol and phthalic anhydride with sulfuric acid. Pure phenolphthalein forms small crystals that dissolve in alcohol or ether. It turns red in the presence of an alkaline substance.

As a laxative, phenolphthalein is the active ingredient in many medicines. It is one of the least poisonous of common laxatives, but some people are allergic to it. Thus, it must be used with care. Patrice C. Bélanger

Phenomenology, *fuh NAHM uh NAHL uh jee,* is a philosophy that was developed by the German philosopher Edmund Husserl in the early 1900's. Husserl wanted to understand how consciousness works in order to better understand human experience. Consciousness refers to the power of the mind to be aware of acts, sensations, and emotions. Husserl believed that everything we know about reality derives from our consciousness.

For phenomenologists, experience has two parts. The first part consists of *objects of consciousness* (the things of which one is conscious). Objects of consciousness, which include material objects, ideas, and wishes, are called *phenomena.* The second part of experience consists of *acts of consciousness,* such as perceiving, believing, thinking, and desiring. Phenomenologists believe that all acts of consciousness are related to objects of consciousness and thus must also be considered phenomena. This relationship is called *intentionality.*

The phenomenological method starts with the theory that people normally make certain assumptions about their experiences. They consider the things they have been taught, and remember past experiences. Such presuppositions limit their experiencing of phenomena. Phenomenologists realize that it is impossible to entirely

iminate these presuppositions from the mind. Instead, ey try to expand their experiencing of phenomena by ealing with the presuppositions critically. One critical ethod involves *fantasy variations.* The philosopher var-s the presuppositions, imagining how the experience ould be perceived under varying circumstances. The atures of the experience that remain constant despite e variations are considered its *essence.*

Husserl has had many followers. They include the ench psychologist Maurice Merleau-Ponty and the erman philosopher Martin Heidegger. Both men ar-ued that phenomenology should not be limited to an nalysis of consciousness. Instead, they used the phe-omenological method to analyze human existence in eneral. The method has also been successfully applied specific fields, such as anthropology, law psychiatry, sychology, religion, and sociology. Don Ihde

henylketonuria (PKU), *FEHN uhl KEE tuh NYUR ee h,* is a hereditary disease that results in mental retarda-on unless treated during early infancy. It occurs chiefly people of western European ancestry. The bodies of eople with PKU accumulate too much *phenylalanine,* ne of the amino acids that make up proteins. For un-nown reasons, an excess of phenylalanine in an infant's ody harms development of the brain and intelligence.

PKU is caused by a *mutation* (change) in a gene that al-rs the function of the enzyme *phenylalanine hydroxy-se.* This enzyme normally converts phenylalanine to e amino acid *tyrosine.* In PKU patients, the conversion oes not take place properly. Phenylalanine is an essen-al part of the human diet and it builds up in the bodies f PKU patients who eat normal foods.

Doctors diagnose PKU by testing the infant's blood a w days after birth. An abnormally high level of phenyl-anine may indicate the presence of the disease. Fur-ier laboratory tests confirm the diagnosis.

In treating PKU, doctors prescribe a diet low in phe-ylalanine. Such a diet includes fruits and certain vege-bles and cereals. Milk, milk products, meat, fish, and ther high-protein foods should be avoided. Treatment ust begin before the patient is two months old to en-ure normal mental development. Many doctors recom-iend that treatment continue through childhood. Vomen with PKU may follow a special diet before and uring pregnancy to protect the brain development of n unborn baby. Charles C. Black and Charles R. Scriver

heromone, *FEHR uh mohn,* is a chemical substance eleased by many kinds of animals to communicate with ther members of their species. The animals that se-rete pheromones range from one-celled organisms to iesus monkeys and many other mammals.

Both males and females use pheromones to establish rritories, warn of danger, and attract mates. For exam-le, certain ants, mice, and snails release *alarm phero-ones* when injured or threatened. The odor warns ther members of the species to leave the area. A heromone secreted by the queen bee of a hive pre-ents all the other females in the group from becoming exually mature. The queen then becomes the only bee the hive that can mate and lay eggs. Scientists have iscovered evidence of pheromones in human beings ut do not know whether they affect human behavior.

Since 1959, chemists have developed synthetic phero-iones that are used to control insect pests. Unlike many pesticides, pheromones do not harm the environment. Artificial female pheromones of such insects as moths and beetles are used to bait traps that capture males of the same species. In another method of pest control, called *communication disruption,* farmers spread their crops with fibers soaked in an insect pheromone. The odor of the pheromone prevents the male insects from finding the females for mating. George B. Johnson

Phi Beta Kappa, *FY BAY tuh KAP uh,* is a college and university honor society that encourages scholarship in the liberal arts and sciences. It is the oldest American fraternity with a Greek-letter name. Both men and women can belong to it.

WORLD BOOK photo

Phi Beta Kappa key

Phi Beta Kappa was founded in 1776 at the College of William and Mary, Williamsburg, Va. It was first organized as a secret society devoted to literary and philosophical discussion. During the 1800's, the organization abandoned secrecy and became an honor society. Today, members are elected primarily by Phi Beta Kappa college faculty. They select new members from seniors and juniors with high academic records. Membership is sometimes conferred for scholarship after graduation. The letters ΦBK (Phi Beta Kappa) are the initials of the Greek words Φιλοσοφία Βίου Κυβερήτης, meaning *Philosophy* (*is*) *the Guide of Life.*

Phi Beta Kappa has active chapters at about 240 colleges and universities in the United States, and a living membership of about 425,000. Its regular program includes scholarships and book awards, sponsored by individual chapters, graduate associations, and the national organization. It publishes two magazines: *The Key Reporter,* for members, and *The American Scholar,* for all interested persons. The national organization, called the Phi Beta Kappa Society, has headquarters in Washington, D.C. Critically reviewed by the Phi Beta Kappa Society

Phidias, *FIHD ee uhs* (490?-420? B.C.), was the greatest sculptor in ancient Greece. His artistry was largely responsible for the High Classical style of sculpture during the Golden Age of Athens in the 400's B.C.

Phidias is best known for his designs for the sculptures on the Parthenon. Phidias conceived and designed these works, though he may not have actually made them. He created statues of gods and goddesses primarily in marble, but occasionally in gold and ivory. These statues were unrivaled in the ancient world for their majesty and grandeur.

None of Phidias' statues survive, but ancient authors describe a great gold and ivory statue of Athena Parthenos. It stood in the Parthenon and was more than 35 feet (11 meters) high. Phidias was most famous for his gigantic gold and ivory statue of the seated Zeus, ruler of the gods. This statue was created for the temple at Olympia. Marjorie S. Venit

Philadelphia's City Hall is one of the largest city halls in the United States. On top of its huge tower stands a statue of William Penn, the English Quaker who founded the city.

Philadelphia

Philadelphia is the birthplace of the United States. The Declaration of Independence and the Constitution of the United States both were signed in Philadelphia's historic Independence Hall. The city was the capital of the American Colonies during most of the Revolutionary War in America (1775-1783).

Philadelphia is Pennsylvania's largest city and one of the largest cities in the United States (see **United States** [table: The 50 largest cities]). It lies in southeastern Pennsylvania on the Delaware River. The river flows into the Atlantic Ocean and helps make Philadelphia one of the nation's busiest freshwater ports. The city is also a national center of culture, education, finance, and health care. The Philadelphia area is a center of the pharmaceutical industry in the United States.

William Penn, an English Quaker, founded Philadelphia in 1682. Penn, who had been persecuted for his Quaker beliefs, planned Philadelphia as a center of religious freedom. The word *philadelphia* means *brotherly love* in Greek, and Philadelphia was nicknamed the City of Brotherly Love. It also became known as the Quaker City because many of its first settlers were Quakers. Today, the American Quakers have their headquarters in Philadelphia. During the 1700's, Philadelphia developed into the largest, wealthiest city in the American Colonies.

Few cities in the United States can match Philadelphia's historic attractions. Every year, millions of visitors thrill to the sight of Independence Hall and the Liberty Bell. Many visitors enjoy touring Carpenters' Hall and Congress Hall, where Benjamin Franklin, Thomas Jefferson, and other early leaders laid the foundations of a new nation. Philadelphians also take pride in the city's world-famous orchestra, excellent colleges and universities, scenic parks, and outstanding museums.

Philadelphia faces problems common to many other large industrial cities. During the last half of the 1900's, many manufacturing companies closed or moved out of the city, resulting in the loss of tens of thousands of jobs. During the same period, the population decreased by hundreds of thousands of people. The loss of jobs and people left the city's working-class neighborhoods with numerous closed factories and block after block of abandoned homes. Jobs are available in high-technology firms that have begun operations in Philadelphia's fast-growing suburbs. But many city residents lack the necessary education for these jobs and even the transportation to reach them.

Philadelphia's leaders have been working to expand tourism to help revive the city's economy. By highlighting the area's historical significance, they have encouraged investments in such projects as new hotels and restaurants.

The city

Philadelphia covers 144 square miles (373 square kilometers), including 9 square miles (23 square kilometers) of inland water. It lies in Philadelphia County, but the city and the county have the same boundaries. Thus, Philadelphia is both a city and a county.

The Delaware River runs east and south of Philadel-

hia and separates it from New Jersey. The Schuylkill ›ronounced *SKOOL kihl)* River flows through Philadelhia and into the Delaware River at the southern edge f the city. Downtown Philadelphia, called Center City, es between the two rivers. Philadelphia's chief residenal districts are north, south, and west of Center City.

Downtown Philadelphia. Philadelphia's huge City lall covers about 5 acres (2 hectares) in the center of owntown. It is one of the largest city halls in the United tates. A tower rises from the front of the white granite nd marble building. A bronze statue of William Penn n top of the tower ranks as the world's largest sculpure atop a building. The statue is 37 feet (11 meters) tall nd weighs 53,523 pounds (24,278 kilograms). The disance from the ground to the top of the statue is nearly 48 feet (167 meters). Philadelphia's chief city governnent buildings border the streets around City Hall.

South of City Hall is a section of Broad Street called ne Avenue of the Arts. This street is home to a number f the city's arts organizations, including the Philadelhia Orchestra, the Opera Company of Philadelphia, and ne Pennsylvania Ballet. Fashionable shops and expenive restaurants spread west of the arts district along Valnut Street and around Rittenhouse Square.

The area west of City Hall has become a district of skycrapers. Until 1984, no building rose higher than the tatue of Penn. Since 1984, however, the Philadelphia kyline has changed greatly. Several office buildings in ne area west of City Hall tower 50 stories or more.

Northwest of City Hall, four of Philadelphia's finest nuseums stand near the Benjamin Franklin Parkway, a eautiful treelined boulevard modeled after the Champs lysées in Paris. These museums are the Academy of Jatural Sciences of Philadelphia, the Franklin Institute, he Rodin Museum, and the Philadelphia Museum of \rt. The parkway ends near the entrance to Fairmount 'ark. One of the nation's largest city-owned parks, Fairnount Park stands along the Schuylkill River and Wisahickon Creek. The art museum neighborhood in-ludes dozens of blocks of historic homes along narow, treelined streets. Northeast of City Hall are Chinaown and the large Pennsylvania Convention Center.

Philadelphia's chief historic area lies east of City Hall. It enters on the 22-acre (9-hectare) Independence Nation-l Historical Park, which includes Independence Hall. Inide this handsome red brick building on Chestnut itreet, visitors may see the room where the Declaration of Independence and the Constitution were signed. The amous Liberty Bell hangs in a pavilion across from Inlependence Hall. Nearby are Congress Hall, the home of Congress from 1790 until 1800; and Carpenters' Hall, vhere the First Continental Congress met in 1774.

Other famous structures stand throughout the historic irea. The Betsy Ross House on Arch Street is where the amous seamstress may have made what became the irst United States flag in 1777. Christ Church, an Episco-al church built on Second Street between 1727 and 744, contains the pews of Benjamin Franklin, George Vashington, and other famous Americans. About 35 rick houses built during the early 1700's line Elfreth's \lley, a narrow, block-long cobblestone street between \rch and Race streets. It is the nation's oldest street of ontinuously occupied homes. On Fifth Street, the argest United States Mint produces hundreds of millions of dollars worth of coins each year.

Symbols of Philadelphia. The city's flag was adopted in 1895. The city seal, *right,* appears on the flag. The seal, which was adopted in 1874, includes Philadelphia's motto, *Philadelphia Maneto,* which means *Let Brotherly Love Continue.*

the Balch Institute for Ethnic Studies; and the National Museum of American Jewish History. The historical area is also the site of Old City, Philadelphia's oldest neighborhood. Artists helped to revitalize the neighborhood, formerly an industrial area. Old City now includes many galleries, antique shops, and cafes.

Residential districts. Society Hill, one of Philadelphia's chief historic neighborhoods, lies south of Independence National Historical Park. Society Hill includes hundreds of restored 200-year-old homes, and many blocks look much as they did in colonial times. Historic churches there include St. Mary's Church, a Roman Catholic church built in 1763; Old Pine Street Presbyterian Church, erected in 1768; and Mother Bethel African Methodist Episcopal Church, built in 1818. Modern town houses and apartment buildings stand nearby in sharp contrast to the old structures.

Directly south of Society Hill is Southwark, the oldest section of Philadelphia. Swedish immigrants settled there during the early 1600's. Gloria Dei (Old Swedes') Church, Pennsylvania's oldest church, opened in the area in the 1640's.

The southern section of Philadelphia includes the neighborhood of South Philadelphia. People of Italian descent once made up the largest ethnic group in this neighborhood. The colorful, lively outdoor Italian Market still attracts shoppers from throughout the city and suburbs. Many people from Southeast Asia have moved here, and Italian restaurants now share the neighborhood's narrow streets with Thai and Vietnamese restaurants. Farther south stand three stadiums that make up Philadelphia's main sports complex. Philadelphia International Airport lies southwest of the sports complex.

University City, a neighborhood across the Schuylkill River and west of Center City, has a notable complex of hospitals and universities. These facilities include Drexel University, the University of Pennsylvania, the University of Pennsylvania Hospital, and the internationally known Children's Hospital of Philadelphia. The West Philadelphia neighborhood lies west of University City.

Row houses are the most common type of housing in Philadelphia. Each of these houses shares at least one wall with the house next door. Most of the structures are two- or three-story brick buildings.

North Philadelphia borders Center City on the north. Many of the neighborhoods in this area have declined, and many of the residents are among the city's poorest people. African American churches have played a large role in rebuilding these neighborhoods. The Opportunities Industrialization Center, a noted private job-training center, is in North Philadelphia. African American businesspeople own and operate Progress Plaza, a nearby shopping center. Temple University is also in North Philadelphia.

Neighborhoods farther north include Manayunk, Germantown, and Chestnut Hill. Manayunk, along the Schuylkill River, was once a neighborhood of textile mills. It is now home to many popular shops and restaurants. Dutch and German Quakers founded Germantown in 1683. The community remained independent of Philadelphia until 1854. Germantown's historic buildings include Cliveden, an elegant mansion built in 1767; and the Deshler-Morris House, where President George Washington lived briefly in 1793. Chestnut Hill is an area of mansions and fine shops. Attractive residential neighborhoods with wide streets and modern shopping areas spread over most of the northeastern Philadelphia area.

The metropolitan area of Philadelphia covers 3,586 square miles (9,288 square kilometers). It extends over Bucks, Chester, Delaware, Montgomery, and Philadelphia counties in Pennsylvania and across Burlington, Camden, Gloucester, and Salem counties in New Jersey. The metropolitan areas of Atlantic City, Philadelphia, and Wilmington form the Philadelphia-Wilmington-Atlantic City Consolidated Metropolitan Statistical Area.

Philadelphia's best-known suburbs include old, elegant communities called Main Line towns. They lie west of the city along what was once the main line of the Pennsylvania (now Penn Central) Railroad. These communities include Ardmore, Devon, Paoli, and the college towns of Bryn Mawr, Haverford, and Villanova.

The metropolitan area includes three famous Revolutionary War sites. At Brandywine Battlefield, southwest of Philadelphia, the British defeated American forces in September 1777 and went on to capture Philadelphia. Valley Forge National Historical Park, west of the city, occupies the site where the colonial army camped during the difficult winter of 1777. Washington Crossing State Park, north of Philadelphia, marks the site where General George Washington and his troops crossed the Delaware River by night to make a surprise attack on the Hessians at Trenton, New Jersey, in 1776.

The people

Ethnic groups. English and Welsh Quakers who accompanied William Penn were the first settlers in Philadelphia. Other Europeans followed in three major waves of immigration. Many English people arrived throughout the 1700's. In the second wave, from the 1830's to the 1880's, large numbers of families came from England, Germany, Ireland, Scotland, and Wales. In the third wave, in the early 1900's, many immigrants came from Austria, Hungary, Italy, Poland, and Russia.

Blacks began to come to Philadelphia during the 1600's because of the Quaker belief in racial equality. African Americans from the Southern States started to migrate to the city in large numbers during and after World War I (1914-1918).

Today, about half of the people of Philadelphia have European ancestry, and most of the rest are African Americans. Other residents include people of Hispanic or Asian backgrounds.

Education. Philadelphia has more than 250 public schools. The city's private and parochial schools include Catholic, Jewish, and Quaker schools.

Philadelphia has about 20 colleges and universities. The Pennsylvania Academy of the Fine Arts, founded in Philadelphia in 1805, is the oldest art school in the United States. The Moore College of Art, the nation's oldest art school for women, opened in the city in 1844. The first U.S. medical school that admitted only women was the Woman's Medical College of Pennsylvania, established in Philadelphia in 1850. It began to admit men in 1969 and is now part of MCP Hahnemann University.

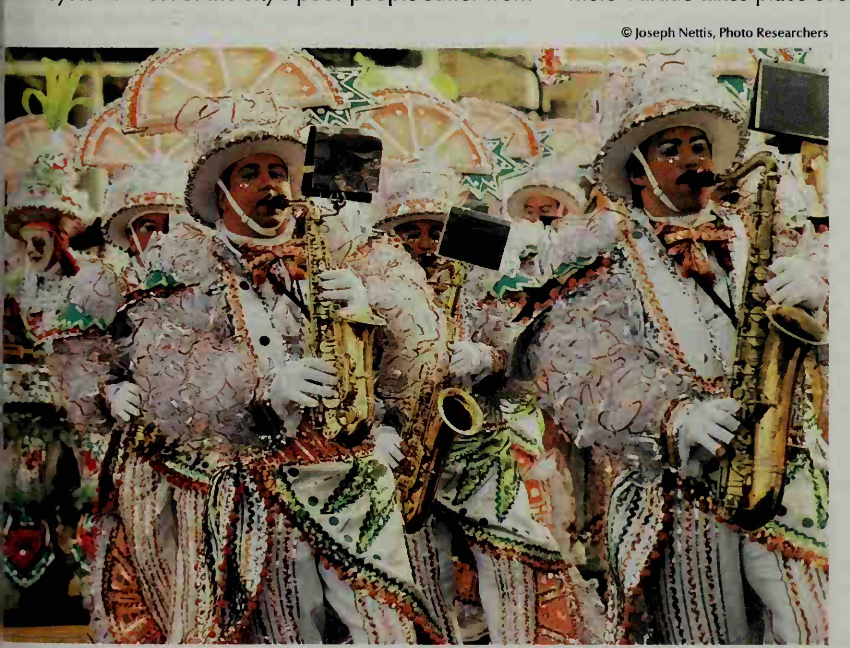
Philadelphia also has a number of other medical
hools and ranks among the country's leading medical
nters. The University of Pennsylvania, located in
iladelphia, was founded in 1740 and began granting
chelor's degrees in 1757. It is the sixth oldest universi-
in the United States. Temple University is Philadel-
ia's largest institution of higher learning, and it is a
ajor research institution. Other colleges and universi-
s in the city include Drexel, La Salle, and St. Joseph's
iversities.

About 30 colleges and universities are near Philadel-
ia. One of them, Bryn Mawr College, was one of the
st U.S. colleges for women. It was established in 1885.
her schools near the city include Haverford and
varthmore colleges and Villanova University.

Housing. More than 60 percent of Philadelphia's fami-
s own their homes. Most of the rest rent apartments.
ick town houses called row houses are the most com-
on type of housing in the city. These homes line entire
eets in parts of Philadelphia. Each has two, three, or
ur stories and shares at least one wall with the house
xt door. Many of Philadelphia's most expensive homes
e in Chestnut Hill, in the northwestern part of the city,
d in Society Hill, a part of Center City. Center City has
number of high-rise apartment buildings.

Thousands of Philadelphians with low incomes lack
cent housing. Many of them live in decaying apart-
ent buildings and row houses in North Philadelphia,
uth Philadelphia, and West Philadelphia. Thousands
housing units in run-down buildings are vacant. A
mber of the owners have died. Other owners have
oved away and abandoned houses in declining neigh-
rhoods that they could not sell. Philadelphia has a
ogram that offers certain abandoned buildings at no
st to people who promise to repair and occupy them.

Social problems. Philadelphia, like other large cities,
ces many problems, including poverty, crime, and ille-
l drug use. It struggles with an inadequate public edu-
tion system. Most of the city's poor people suffer from discrimination or lack education and job skills. They live in run-down dwellings. Large numbers have no jobs, and many others work long hours for low wages. Such poor living conditions contribute to the city's crime rate. In addition, the buying and selling of illegal drugs increases the number of violent crimes in the city.



City officials have tried to solve these social problems by improving the public schools, upgrading the police department, and encouraging economic development. Crime has fallen, but many residents of poor neighborhoods still face limited opportunities.

Cultural life and recreation

The arts. The Walnut Street Theatre, one of several professional theaters in downtown Philadelphia, is the oldest active theater in the United States. It presented its first play in 1809. The city's strong theatrical tradition is evident in such professional companies as the Wilma Theater and the Arden Theatre Company and in the experimental plays presented at the University of Pennsylvania and Temple University. The Freedom Theatre is an important part of the city's African American cultural scene. The People's Light and Theatre Company, in suburban Malvern, has won national recognition.

Philadelphia's magnificent Academy of Music, which opened in 1857, is the oldest opera house in the United States still in use. It is the home of the Pennsylvania Ballet as well as the Opera Company of Philadelphia. The Kimmel Center is the home of the Philadelphia Orchestra. The center is also the home of such arts groups as the Chamber Orchestra of Philadelphia and the Philadelphia Chamber Music Society. During the summer, the Philadelphia Orchestra and other musical groups present free outdoor concerts at the Mann Center for the Performing Arts in Fairmount Park.

The Mummers' String Bands, which together form one of Philadelphia's top performing groups, have won fame for their elaborate costumes. The festive Mummers' Parade takes place every New Year's Day.

The Mummers' Parade features marching bands in elaborate and colorful costumes. This festive Philadelphia event is held annually on New Year's Day.

The Rodin Museum in Philadelphia has an outstanding collection of works by th famous French sculptor Auguste Rodin. The collection features one of Rodin's best-known works, *The Burghers of Calais, shown here.*

Libraries and museums. The Library Company of Philadelphia, which Benjamin Franklin helped establish in 1731, became the nation's first library to circulate books for a membership fee. Members of the company paid dues to buy books for the company, which members then could borrow free of charge. Today, the library still owns volumes that once belonged to Thomas Jefferson, William Penn, and George Washington. The Historical Society of Pennsylvania, next door to the library, has one of the finest collections of books on United States history. The American Philosophical Society houses an outstanding research library in Library Hall.

Philadelphia's public library system is called the Free Library of Philadelphia. It has a number of branches and owns a fine collection of rare books.

The four museums near the Benjamin Franklin Parkway rank among the finest in the world. The collection of the Philadelphia Museum of Art includes many superb paintings by French masters. The Rodin Museum exhibits works by the French sculptor Auguste Rodin. The Academy of Natural Sciences, founded in 1812, is the oldest natural-science museum in the United States. It has a world-famous display of stuffed birds and a large dinosaur exhibit. The Franklin Institute, established in 1824, was the nation's first museum of science and technology. It features exhibits on communication, computers, nuclear energy, and space travel. The institute also includes a large-screen theater and a planetarium.

The Pennsylvania Academy of the Fine Arts is the oldest art museum in the United States. This museum opened in 1805 and has many paintings from colonial times. Well-known art galleries in the city include the Philadelphia Art Alliance and the Rosenbach Museum.

The Atwater Kent Museum specializes in the history of Philadelphia. Balch Institute has exhibits on 300 years of immigration to America. Other notable Philadelphia museums include the African American Museum in Philadelphia, the Mummers Museum, the National Museum of American Jewish History, the Independence Seaport Museum, and the Please Touch Museum, which features exhibits and activities for children ages 1 to 7.

Recreation. Philadelphia's park system includes about 325 parks and playgrounds. Fairmount Park is the chief recreational area. In summer, people stroll or ride bicycles along its 45 miles (72 kilometers) of cool, shaded trails. Park visitors also may tour six colonial mansions that have been restored to their original elegance or sip tea in a Japanese teahouse. The Philadelphia Zoo forms part of the park.

Philadelphia has several professional sports teams. They include the Philadelphia Eagles of the National Football League, the Philadelphia Flyers of the National Hockey League, the Philadelphia Phillies of baseball's National League, and the Philadelphia 76ers of the National Basketball Association. The Army-Navy game, one of the most colorful college football rivalries, takes place in Philadelphia in late November or early December.

Economy

Service industries. Most of the city's workers are employed in service industries. Philadelphia's most important service industries are education, finance, health care, and trade.

Educational institutions provide jobs for many of Philadelphia's workers. The city and its surrounding area have dozens of colleges and universities.

Several important financial institutions have their headquarters in the city. They include the Third Federal Reserve District Bank and the Philadelphia Stock Exchange. The U.S. Mint at Philadelphia is one of the two mints that make most of the coins intended for general circulation in the United States. The other mint is in Denver. Philadelphia's commercial banks and insurance companies employ many workers.

Philadelphia's thriving health care industry is based on the approximately 50 hospitals and 6 medical schools in the city. Major hospitals include Thomas Jefferson University Hospital and the Albert Einstein Medical Center. Medical schools include the University of Pennsylvania School of Medicine, MCP Hahnemann University,

ıd the Temple University School of Medicine.

The wholesale trade industry in Philadelphia relies ːavily on the city's port, which is one of the busiest ːshwater ports in the United States. The major prod-ːts shipped through the port are chemicals, food prod-ːts, and petroleum. The large numbers of tourists that ʂit each year strengthen the city's retail trade.

Manufacturing. Philadelphia ranks high in clothing oduction among U.S. cities. The city's clothing industry ıecializes in finishing expensive products from interna-ɔnal factories.

Philadelphia also manufactures chemicals, fabricated etal products, and processed foods. Pharmaceuticals e the city's most valuable type of chemical product. ther leading chemical products include industrial ıemicals and pesticides. The chief processed foods oduced in Philadelphia include bakery products, bev-ages, and candy. The most important fabricated metal oducts are metal containers and sheet metal.

Transportation. Philadelphia International Airport ındles national and international flights. Local and re-onal airlines use the smaller Northeast Philadelphia rport. CSX Transportation and Norfolk Southern Rail-ay provide freight service to Philadelphia. Passenger ains link Philadelphia and cities throughout the coun-y. Four bridges link Philadelphia with New Jersey.

The publicly owned Southeastern Pennsylvania Trans-ɔrtation Authority provides most local transportation in e city. It operates buses, elevated and subway trains, reetcars, and trolley cars, and it administers commuter ilroad service.

Communication. Benjamin Franklin helped Philadel-ıia become a leading communication center of the merican Colonies. He published the *Pennsylvania azette,* a newspaper, from 1729 to 1766. Franklin also ublished *Poor Richard's Almanac,* a witty journal, every ːar from 1733 to 1758. The first magazine in America, *he American Magazine,* was published in Philadelphia 1741. The nation's first daily newspaper, the *Philadel-hia Evening Post and Daily Advertiser,* began publish-g in the city in 1783. Today, Philadelphia has two major daily papers, *The Philadelphia Inquirer* and *The Philadel-phia Daily News.*

Government

Until 1952, the city government of Philadelphia need-ed the approval of the Pennsylvania General Assembly to levy taxes and to act on many other local matters. That year, under a new charter granted by the state, the city gained *home rule* (self-government).

Philadelphia has a mayor-council form of government. The voters elect the mayor and the 17 members of the City Council to four-year terms. The mayor may serve any number of terms, but not more than two in a row.

Philadelphia's mayor has broad powers. The mayor appoints most of the city's chief administrative officials, plans improvement projects, prepares the city budget, and can veto laws passed by the council.

The council's chief duty is to make the city's laws. The council also decides how the city government spends its money. Any bill vetoed by the mayor becomes law if the council repasses it by a two-thirds vote.

Most of the city's income comes from taxes on prop-erty and wages. The city taxes the wages of everyone who either works or lives in Philadelphia. But taxes and other local sources of revenue do not meet all the city government's expenses. As a result, Philadelphia relies on grants from the state and federal governments to pay for many major improvements.

History

The Delaware Indians lived on the site of what is now Philadelphia long before Europeans arrived. British and Dutch sailors visited the area in the early 1600's. In the 1640's, Swedish families established the first permanent settlement there. The Dutch, English, and Swedes fought over the area, and England finally won control of it in 1674.

Early colonial days. In 1681, King Charles II of Eng-land granted William Penn a charter to establish what became the Pennsylvania Colony. Penn chose the site of Philadelphia for the capital, which he visualized as a

"greene countrie towne." He arrived there in 1682, and the town became the capital of Pennsylvania in 1683.

Penn had advertised his guarantee of religious liberty before he left Europe, and thousands of persecuted people came to Philadelphia. The town also quickly acquired a reputation for offering economic opportunity. As a result, Philadelphia attracted thousands of other Europeans who were fleeing famine, poverty, or war. The Philadelphia area had a population of about 4,500 by 1700. Philadelphia was incorporated as a city in 1701.

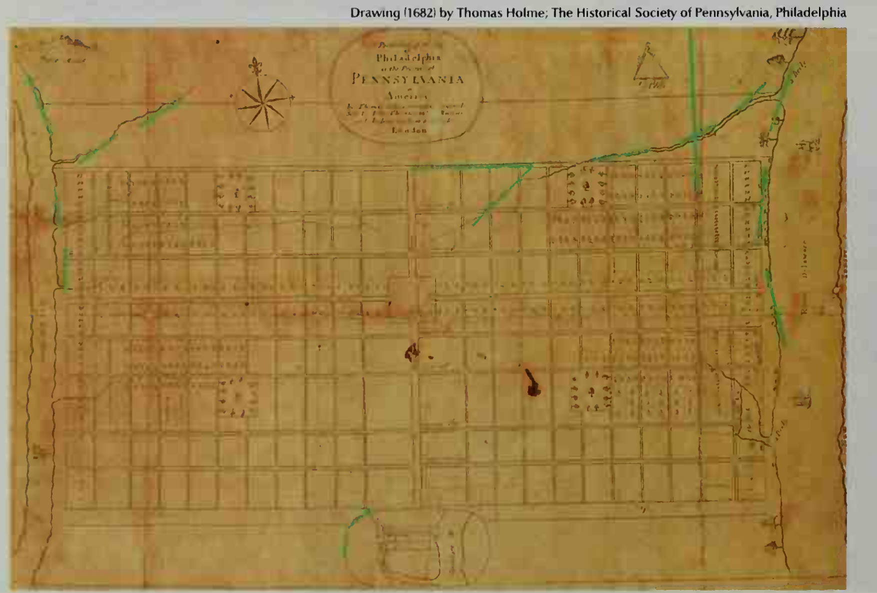
Philadelphia's location near important land and water trading routes helped it become a prosperous manufacturing and shipping center. During the early 1700's, the city developed into the leading industrial center and busiest port in the American Colonies.

In 1723, a 17-year-old apprentice printer named Benjamin Franklin moved to Philadelphia from Boston. Within a few years, he had become Philadelphia's most famous civic leader. His newspaper and almanac helped make the city a major publishing center. By 1760, the Philadelphia area had a population of about 20,000. It was the largest city in the colonies.

The Revolutionary War period. Philadelphia became a center of colonial protest during the mid-1700's, when the United Kingdom adopted taxes and trade policies that angered the Americans. In 1774, the First Continental Congress met in Carpenters' Hall. Its delegates criticized British laws that they thought violated the colonists' rights. In May 1775, after the opening battles of the Revolutionary War, the Second Continental Congress assembled in the Pennsylvania State House (now Independence Hall). It adopted the Declaration of Independence there on July 4, 1776. Thomas Jefferson had written the Declaration in Philadelphia in June of that year. Congress met in the city during most of the war.

British troops captured Philadelphia on Sept. 26, 1777, shortly after winning the Battle of Brandywine. American forces tried to recapture the city, but the British defeated them in the Battle of Germantown on Oct. 4, 1777. In 1778, France joined the Americans in the war and sent a fleet to aid the colonists. On June 18, 1778, the British withdrew from Philadelphia to avoid being trapped there by the French fleet. Congress met in the city again from July 1778 until June 1783. Two Philadelphia financiers, Robert Morris and Haym Salomon, raised great amounts of money to aid the American effort in the Revolutionary War.

In 1787, delegates to the Constitutional Convention signed the Constitution of the United States in Independence Hall. Philadelphia served as capital of the United States from 1790 until 1800, when Washington, D.C., became the capital. By 1790, the population of the Philadelphia area had risen to about 42,000, the largest in the nation. In 1793, Philadelphia suffered one of its greatest disasters when a yellow fever epidemic killed almost 5,000 of its people. In 1799, the Pennsylvania legislature moved the state capital from Philadelphia to Lancaster, which served as the capital until Harrisburg was named the capital in 1812.



Industrial beginnings. During the early 1800's, the development of coal mines northwest of Philadelphia provided a huge fuel supply and helped attract industries to the city. The construction of canals, railroads, and roads increased trade between Philadelphia and the Midwest. Philadelphia industries produced clothing, iron, locomotives, machinery, ships, shoes, and textiles.

The city's rapid industrialization drew thousands of German and Irish immigrants to Philadelphia during the mid-1800's. Competition for jobs among the newcomers and those already in the city caused tension. In 1844, riots between native-born Protestants and Catholic immigrants from Ireland caused about 30 deaths. Many blacks were also killed in riots.

Eleven nearby towns became part of Philadelphia in 1854, when the state legislature merged the city and Philadelphia County. By 1860, the city had a population of 565,529.

During the mid-1800's, Philadelphia became a center of the antislavery movement. In 1833, the abolitionist reformer Lucretia C. Mott and other Philadelphians

rmed the American Anti-Slavery Society. Two black iladelphia businessmen, James Forten and Robert ırvis, became abolitionist leaders. During the Ameri- ın Civil War (1861-1865), a Philadelphia banker, Jay oke, was the Union's chief financial agent. The city's dustries boomed with the production of war materials.

A growing city. In 1876, Philadelphia held the Cen- nnial Exposition, a world's fair that marked the 100th ıniversary of the adoption of the Declaration of Inde- endence. The exposition was the first successful orld's fair in the United States.

Industry and commerce continued to expand in iladelphia during the late 1800's. Leading Philadelphia ısinessmen, including the financier Anthony J. Drexel ıd the merchant John Wanamaker, helped develop a owntown shopping district on Market Street. In the 390's, a system of electric trolley cars enabled many iladelphians to move far from the downtown area.

During the late 1800's and early 1900's, an increasing emand for factory workers attracted thousands of East- n European Jews and Italians to Philadelphia. African mericans from the Southern States began to migrate to e city in large numbers at the time of World War I 914-1918). Philadelphia's population soared from about 50,000 in 1880 to more than 1,800,000 in 1920. Thou- ınds of African Americans settled in Philadelphia dur- g and after World War II (1939-1945) in hope of finding bs and escaping racial violence. The city's population eaked at more than 2 million in 1950.

Urban renewal. Philadelphia launched a vast urban newal program in the late 1940's. The city cleared hun- reds of acres of residential and industrial structures. ne Penn Center, an office complex, rose west of City all in an area where there had once been railroad acks. In the mid-1950's, the program was expanded to ear space for hospitals, universities, and other institu- ons. With the help of the federal and state govern- ıents, the city tore down three entire blocks of old uildings north of Independence Hall and replaced em with a spacious landscaped area. The city built ublic housing projects to house the tens of thousands f poor Philadelphians who lost their neighborhoods uring these urban renewal efforts.

African American Philadelphians led by Leon H. Sulli- ın, minister of Philadelphia's Zion Baptist Church, be- an to develop a number of major economic self-help rojects in the 1950's. In 1964, Sullivan founded the Op- ortunities Industrialization Center to help train African mericans for jobs.

Continued growth. During the 1970's, developers unched several major projects in Center City. An en- osed shopping mall known as Gallery I opened in 1978 s part of the Market Street East development near City all. A second mall, Gallery II, opened in the early 1980's. ne Market Street East project also includes the massive ennsylvania Convention Center, which opened in 1993. ı 1986, a marina and a marine trade center were com- leted as part of the Penn's Landing complex on the elaware River. In 1991, the city created the Center City istrict, where businesses supported a successful effort clean up downtown.

In 1983, Philadelphia voters elected the city's first frican American mayor, W. Wilson Goode. Goode was elected in 1987. He served as mayor until 1992.

Recent developments. The end of the 1900's brought a reevaluation of the massive urban renewal that had taken place in the 1950's and 1960's. Critics pointed out that it had been wrong to move the poor into unattractive public housing projects. The city began tearing down most of the public housing high-rises.

Philadelphia turned to tourism to improve its economy. The city focused on promoting its matchless historical sites and institutions and encouraging new restaurants and hotels. Philadelphia became known for fine dining. Several new hotels opened for the Republican National Convention of 2000, which the city hosted. However, most of the area's highest paying jobs remained in the suburbs. Morris J. Vogel

Philadelphia, *FIHL uh DEHL fee uh,* was the name the ancient Greeks gave to several cities. The name means *brotherly love.* One Philadelphia was a town in Lydia founded in the 100's B.C. by King Attalus II Philadelphus of Pergamum. It was a center of early Christianity. Alaşehir, Turkey, stands on the site now. Another ancient Philadelphia, in Palestine, began as a city called Rabbath-Ammon. But the Egyptian king Ptolemy II Philadelphus conquered it, renamed it, and introduced Greek customs and culture. The capital of Jordan, Amman, stands on this site. Thomas W. Africa

Philadelphia Naval Base, Pennsylvania, houses major United States naval activities in the Philadelphia area. It covers 1,275 acres (516 hectares) along the banks of the Delaware River. Operations under the base's command include a damage control training center, a school for boiler-room crews, and an ammunition depot. A shipyard operated there from 1801 to 1996. The naval base also serves as Fourth Naval District headquarters. The district operates an air engineering center and a home for aged and disabled Navy veterans. W. W. Reid

Philanthropy, *fuh LAN thruh pee,* is the promotion of the well-being of human beings by individuals and groups who contribute their services or dedicate their property and money. Philanthropy differs from charity in that it usually helps a large group or an institution, rather than one or a few individuals.

Nearly all civilizations have practiced some type of philanthropy. The ancient Jews levied a *tithe* (tax) for the poor. In ancient Egypt and Greece, royal families gave gifts to establish libraries and universities. The medieval church supported hospitals and orphanages.

In Anglo-Saxon law, the legal basis of philanthropy rests on the Statute of Charitable Uses, passed in England in 1601. The statute approved governmental aid to poor, aged, and orphaned people. It also provided for assistance to hospitals, schools, and universities.

In the United States, gifts from private donors helped establish many early churches, colleges, and hospitals. For example, gifts helped create and support Harvard College. In 1790, Benjamin Franklin established a fund to aid worthy young men. In 1829, James Smithson set aside money for the creation of the Smithsonian Institution (see **Smithsonian Institution**).

Philanthropy has played an increasingly important role in U.S. society since the American Civil War. People of large fortunes, such as John D. Rockefeller and Andrew Carnegie, established foundations that have worked to better humanity nationally and internationally. The contributions of such people have set an example for the public, which contributes billions of dollars annually through benevolent and civic agencies. Joseph C. Kiger

Philemon, *fuh LEE muhn,* **Epistle to,** is the 18th book of the New Testament. It is a letter from the apostle Paul to Philemon, a Christian associate of Paul. The apostle wrote the letter from prison, possibly in Rome, about A.D. 60. The letter was carried by Onesimus, a slave who had run away from Philemon, whom Paul was sending back to his owner. Paul asks Philemon not to punish Onesimus and seems to suggest that Philemon send Onesimus back to Paul to work with him. The Epistle is the shortest of Paul's letters. Terrance D. Callan

Philip II (1165-1223) of France was one of the most important kings of the Capetian dynasty, which ruled France from 987 to 1328. He succeeded his father, Louis VII, in 1180. A clever statesman, Philip not only expanded the kingdom of France but also made the monarchy powerful. He is also known as Philip Augustus.

Philip's first triumph was adding the regions now known as Artois and Picardy to his kingdom. He obtained Artois as part of his wife's *dowry* and Picardy as a result of a dispute with his wife's uncle, the Count of Flanders. A dowry is a wedding gift from the bride's family to the groom. Philip then decided to gain the English possessions in what is now France for himself. In 1189, Philip and the English king Richard the Lion-Hearted went together on the Third Crusade. But Philip quarreled with Richard and returned home. He took advantage of Richard's absence to gain control of some of the English territory in France.

In 1194, Richard returned from the crusade and began a war against Philip in which Richard regained control of most of the English lands in France. Richard was killed in battle in 1199. His brother, King John, went to war against Philip in 1202. Philip took advantage of John's mistakes and conquered most of the English holdings in France. Philip's victory against John's Flemish and German allies at the Battle of Bouvines in 1214 established his hold on the conquered regions.

Philip II (382-336 B.C.) was a great Macedonian king who became master of Greece. He was the father of Alexander the Great, who carried out many of his father's

eams of conquest. See **Alexander the Great.**

Philip, the youngest son of Amyntas II, was born in la. In his early youth, he spent several years as a stage in Thebes. While in Thebes, Philip learned ich of military science from the foremost military ders of the time.

Philip was named regent for his nephew in 359 B.C. en his older brother died. But Philip soon made him-f king. Within two years, he put down all opposition d established himself securely on the throne.

Philip immediately began to carry out his plans of nquest by attacking the Greek towns on his border. had reorganized the Macedonian army so that it was perior to the Greek armies. He used the heavy phalanx mation of attack as a striking arm and heavy cavalry the knockout blow. He developed the light infantry d light cavalry and used them in an all-out pursuit ich destroyed his opponents. Within a few years, ilip controlled most of the small states in Greece. His wer extended as far north as the Danube River.

n Athens, Demosthenes understood Philip's plans, d he thundered forth against Philip in his famous eeches, which came to be known as the *Philippics.* t the Athenians refused to listen to Demosthenes. ey did not believe Philip was a threat to Athens, be-use he was at war with Thrace at the time. In 338 B.C., mosthenes was finally able to rouse the Athenians, d they joined with Thebes in a defensive league ainst Philip. But the Macedonian king completely de-ted the allied armies in the battle Chaeronea that me year, and ended the independence of the Greek y-states.

Philip formed Greece into the League of Corinth, a po-cal organization. All the cities were included except arta, which had never been conquered. The cities re represented in the *Synhedrion* (council) by popula-n and districts. Non-Greek nations were allowed to n. Philip was chosen by the League to command the Greek forces to attack Persia. He was killed while preparing for this war. Thomas W. Africa

Philip II (1527-1598) was a Spanish king who ruled one of the largest empires ever created. He belonged to the Habsburg (or Hapsburg) royal family. In 1555 and 1556, Philip's father—who ruled Spain as Charles I and the Holy Roman Empire as Charles V—gave up his crowns. Philip became king of Spain and ruler of lands that included what are now Belgium, the Netherlands, part of Italy, and much of Central and South America.

Philip spent much of his reign at war defending his empire. Spain, Venice, and their allies defeated the Ottoman fleet at the Battle of Lepanto, near Greece, in 1571. Philip absorbed Portugal into Spain in 1580. But the Netherlands, one of Spain's most valuable possessions, rebelled in the 1560's and declared its independence in 1581. England aided the Dutch rebels. Sir Francis Drake and other English captains also looted Spanish possessions in Central and South America. Philip assembled a fleet of ships so powerful that it was called the Invincible Armada and sent it against England in 1588. The Armada failed to achieve its goals. Philip's many wars strained Spain's resources and contributed to its slow decline in the 1600's.

Philip considered himself the champion of the Roman Catholic faith and strongly supported the Inquisition, which punished Christians accused of holding views opposed to those of the church. He also built El Escorial, a palace and religious center near Madrid.

Philip was born on May 21, 1527, at Valladolid, Spain. The Philippine Islands, where Spain established a colony in 1565, were named after him. Marvin Lunenfeld

Philip IV, *left,* received the homage of King Edward I of England, *kneeling,* in 1286, a year after Philip became king of France.

Philip challenged the power of Pope Boniface VIII in 1301 by arresting a French bishop whom Boniface had appointed. In 1302, Philip taxed Roman Catholic churches against the pope's orders. Philip's actions were approved by the first Estates-General, a body of Frenchmen he called together in 1302. This group, which included representatives of the clergy, nobility, and middle class, was the ancestor of the French Parliament. Philip had Boniface arrested at Anagni, Italy, in 1303. But the townspeople freed the pope. In 1305, Philip arranged the election of a French archbishop as pope. The new pope, Clement V, moved to Avignon, France, in 1309 and carried out Philip's orders, which included persecuting the Knights Templars, a wealthy military order with strong ties to the papacy. Philip V (1683-1746) became king of Spain in 1700. He was the first in a series of Spanish kings from the royal Bourbon family of France. Philip was born a French prince, Duke Philip of Anjou, in Versailles, France. He inherited the throne of Spain from his grandmother's brother, Charles II, who died childless. Other nations feared French control of the Spanish throne and refused to recognize Philip as king. In 1701, Austria, England, the Netherlands, and several German states declared war on France and Spain, and the War of the Spanish Succession began. Philip finally won recognition as king in 1713, but he lost many of his territories to Austria and Britain (see **Succession wars** [The War of the Spanish Succession]). Philip gave up the throne to his son Louis I for eight months in 1724 but returned after Louis died. Philip then ruled until 1746. Marvin Lunenfeld

Philip VI (1293-1350) of France became the first of the Valois line of French kings in 1328. An assembly of barons and church officials chose Philip, a nephew of Philip IV, after Charles IV, the last king of the Capetian dynast had died without leaving a male heir. During Philip's reign, relations with England became hostile. In 1337, Philip declared he would take over Guyenne (Aquitain the land King Edward III of England held in France. Edward III, in turn, a grandson of Philip IV of France, claimed the French throne. These actions began the Hundred Years' War. Philip lost several battles in the war, including an important one at Crécy in 1346. Whe the war ended in 1453, more than a hundred years late the French had driven the English out of almost all of France. A plague epidemic called the Black Death deva tated France in the last few years of Philip's reign. See also **Dauphin; Hundred Years' War.** Sue Helder Golibe

Philip, King (? -1676), became chief of the Wampanoag Indians in 1662. His Indian name was Metacomet. He was the son of Massasoit, the Pilgrims' friend. Philip succeeded his older brother as chief.

As Philip saw the increasing amounts of land taken b the settlers, he grew concerned that the colonists wou in time destroy his people. Soon after he became chief he began preparations to massacre all the white settler in New England. The great struggle known as King Phil ip's War began in 1675. Philip burned both white and In dian settlements. Men, women, and children were kille on both sides. King Philip almost succeeded in wiping out the English settlements in New England. But after the defeat of his forces by the English colonists, Philip was hunted down and killed in a swamp near present-day Bristol, R.I., in 1676. The war then ended in souther New England, but fighting continued in northern New England until 1678. William H. Gilbert

Philip of Bethsaida, *behth SAY ih duh,* **Saint,** was one of the 12 apostles of Jesus Christ. He is prominent in the Gospel of John and was one of the first to be called as an apostle. He was present at the miracle of the feeding of the multitude (John 6: 5-7). When a group of Greeks wanted to see Jesus, they approached Philip for an introduction (John 12: 20-22). At the Last Supper, Philip asked to see the Father. Jesus replied, "He that hath seen me hath seen the Father" (John 14: 8, 9). This special interest in Philip indicates that he was highly regarded by the author of the Gospel of John. Philip should not be confused with Philip the Evangelist, who is mentioned in the Acts of the Apostles.

According to later tradition, Philip preached in Asia Minor (now Turkey), where he was martyred. Philip's feast day in the Roman Catholic Church is May 3. The Eastern Orthodox Churches celebrate his feast day on November 14. Richard A. Edwards

Philippi, *FIHL uh PY* or *fih LIHP eye,* was a city in Macedonia. It stood about 8 miles (13 kilometers) from the Aegean coast, near what is now the Greek city of Kavalla. King Philip II of Macedon founded Philippi in 357 B.C. The city became an important gold-mining center. Mark Antony and Octavian (later Augustus) defeated two of Julius Caesar's assassins, Brutus and Cassius, at Philippi in 42 B.C. Octavian later made Philippi a colony for Antony's supporters who had been expelled from Italy. Philippi was the first city in Europe to be visited by St. Paul. It flourished until about A.D. 600. Philippians, *fuh LIHP ee uhnz,* **Epistle to the,** is the 11th book of the New Testament. It is a letter from the apostle Paul to the Christians in Philippi in what is now northern Greece. Many scholars doubt that Paul wrote the letter in its present form. They believe it consists of three smaller letters from Paul to the Philippians that were combined by a later editor. If Paul wrote the letter in its present form, he did so while in prison, probably in Rome, about A.D. 60. In the Epistle, Paul thanks the Philippians for sending him money. He warns them not to observe the Jewish law and urges them to be at peace with one another. Terrance D. Callan

Traditional and modern ways of life contrast greatly in the Philippines. In northern Luzon, farmers grow crops on mountain terraces said to have been built more than 2,000 years ago by Malay immigrants. In Manila, the capital and largest city, modern buildings rise above a bay.

Philippines

Philippines is an island country in the southwest Pacific Ocean. Its official name is Republic of the Philippines. The Philippines consists of more than 7,000 islands, but only about 1,000 of them are inhabited. The 11 largest islands make up more than 95 percent of the country's area. Manila, the capital of the Philippines, is the nation's largest city and busiest port.

The people of the Philippines are called *Filipinos.* Their ancestors came from what are today Indonesia and Malaysia. Groups of these people formed communities throughout the islands, and each group developed its own culture. As a result, the Philippines has a wide variety of languages, customs, and ways of life.

Spanish explorers colonized the Philippines in the 1500's. They named the islands after King Philip II of Spain. Roman Catholic religious missionaries converted most of the Filipinos to Christianity, but some tribes kept their own religions. Today, the Philippines has more Christians than any other nation of Asia.

Good Friday procession in Manila draws an enormous ɔwd. Almost all the people of the Philippines are Christians, ɔst of them Roman Catholics.

42 to 1944, during World War II, Japanese forces con- ɒlled the islands. The United States granted the Philip- nes independence on July 4, 1946. The new nation opted a Constitution that was similar to that of the nited States. The Philippines struggled to establish a ıble government through much of the late-1900's.

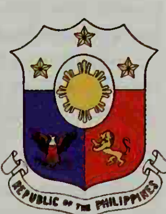
Government

National government is headed by the president. e people elect the president and vice president sepa- ely. The president is limited to one six-year term and e vice president to two consecutive six-year terms. The ngress consists of a Senate and a House of Repre- ntatives. The Senate has 24 members, who are elected six-year terms by the voters of the entire nation. The use has a maximum of 254 members. Voters from dis- cts elect 204 of the representatives to three-year rms. The remaining 50 representatives are selected m lists drawn up by political parties and civic organi- ions to ensure representation of women, ethnic mi- rities, and certain economic and occupational groups. citizens who are at least 18 years old may vote.

Local government. The Philippines is divided into 16 gions, each governed by a regional council. The re- ns are divided into a total of 79 provinces. Every ɔvince has a governor, a vice governor, and a provin- l council. These officials are elected by the people and serve three-year terms.

There are about 60 *chartered cities* in the Philippines. These cities, headed by elected mayors, are governed independently of the provinces. The nation also has about 1,500 *municipalities* (towns). Each municipality is governed by an elected mayor and a council. The Philippines has about 42,000 *barangays* (villages), governed by captains and councils elected by each village.

Courts. The Supreme Court is the highest court in the Philippines. It consists of a chief justice and 14 associate justices. The president appoints all judges.



The Court of Appeals, which reviews decisions made by lower courts, consists of a presiding justice and 50 associates. Every Philippine city has a court. Each municipality has a judge who serves as the local court.

Armed forces. The Philippine Army has about 67,000 members, all volunteers. A navy of 24,000 people and an air force of 16,000 also consist of volunteers. The Philippine National Police has over 100,000 members in a variety of agencies. It cooperates with the armed forces to maintain internal security.

The people

Ancestry. Almost all Filipinos are related to the Malays of Indonesia and Malaysia. Chinese make up the

The Philippine flag and coat of arms feature blue for noble ideals, red for courage, and white for peace. The sun represents independence, and the stars stand for the three main groups of islands. Former Western rule is symbolized on the coat of arms by an eagle representing the United States and a lion representing Spain. The flag was adopted in 1898, and the coat of arms was adopted in 1946.

second largest group in the Philippines, and smaller numbers of Americans, Europeans, Indians, and Japanese also live on the islands. All of these groups have contributed to the Philippine culture, a blend of Asian and Western traditions.

Small groups of Filipinos live in isolated mountain areas. These small groups include the Negritos, whose ancestors settled in the islands about 30,000 years ago.

Languages. The Philippines has two official languages, Filipino (also spelled Pilipino) and English. Filipino is the national language, and it is a required subject in all Philippine elementary schools. Filipino is a variation of Tagalog (pronounced *tah GAH lohg* or *tah GAH log),* the language of the people of the Manila area. More than half the people of the Philippines speak Filipino, and a large number also use Tagalog. About 70 native languages, all of them related to Malay languages, are also spoken in the Philippines.

Almost three-fourths of the people in the Philippines speak some English. The elementary schools and high schools conduct many classes in English, and the universities require students to pass an English examinatio[n] when applying for admission. English is also widely used in commerce and government. In addition, a smal[l] number of Filipinos speak Spanish or Chinese.

Way of life. About 40 percent of the Philippine work[ers] make their living by farming. Much of the farmland belongs to large and medium sized landowners. These owners hire laborers who live and work on the land. Large numbers of people also have jobs in the fishing, lumbering, and mining industries. In the cities, many work in factories or in the service sector.

Most houses in the rural areas stand close together i[n] small clusters. They have wooden walls, and the roofs are made of thatch or corrugated iron.

Wealthy city families live in large houses that are sur[-]rounded by walls. Government-built housing projects are common in the cities. Many poor urban people live

roughly constructed shacks in sprawling slums.
Most Filipinos have large families and maintain a se relationship with all family members, including elr relatives and distant cousins. Men hold most positins of authority at home and in business. But many men work in professional fields. A growing number women work in textile or electronic factories.
Philippine food is a mixture of American, Chinese, alay, and Spanish dishes. Most Filipinos eat rice at ery meal, with beef, fish, or poultry, if they can afford eat. Each region has its own specialties. One popular h, called *adobo,* consists of chicken and pork cooked soy sauce and vinegar. People throughout the islands nk an alcoholic beverage called *tuba,* which is made m the sap of the coconut palm tree.
Most Filipinos wear clothes similar to those worn in st Western countries. On holidays and other special casions, Philippine men wear a *barong tagalog,* a autifully embroidered shirt made of pineapple fiber, v silk, or cotton. Some men wear the barong tagalog work in offices. On special occasions, women may ar a long, puff-sleeved dress called a *balintawak.*
Basketball is one of the most popular sports in the lippines. Other favorite sports include baseball, boxi, and, among the wealthy, golf. Many Filipinos enjoy mbling, much of which is legal in the Philippines. Othpopular recreational activities include *karaoke* ging on stage to recorded music) and movies.

Religion. The Philippine Constitution guarantees freem of worship. About 95 percent of the people are ristians, more than in any other Asian country. Over percent of the population are Roman Catholics. The ion also has many Protestants, Muslims, and mems of the Philippine Independent Church and the lippine Church of Christ.

Education. About 90 percent of Philippine adults can d and write. The law requires children from 7 to 12 rs old to go to school through at least the sixth de. Teachers in the public elementary schools conduct classes in the local language for the first two years and then introduce English and Filipino. Most private schools, high schools, and universities teach in English.
About 25 percent of college-age Filipinos attend college, mostly at private or religious schools. The University of the East, a private institution in Manila, is the nation's largest university.

The arts. The Philippines has produced many painters and writers. Fabian de la Rosa, a popular Philippine artist of the 1800's, painted works showing the everyday life of the people. Fernando Amorsolo, who studied under de la Rosa, became known in the 1900's for his portraits and rural landscapes.
Early Philippine literature consisted mainly of native legends and poems. During the late 1800's, Philippine

writers began examining the heritage of the islanders. Literature played an important part in the Philippine movement for independence in the late 1800's and early 1900's. José Rizal, an early leader of the movement, wrote novels that criticized Spanish authority in the Philippines. The essays of Renato Constantino center on modern Filipinos and their search for a national identity.

Land and climate

Thick forests once covered most of the Philippines. But since the 1950's, extensive lumbering has destroyed most of the forest resources. Narrow strips of lowland lie along the coasts of the islands. The islands of Luzon and Panay have wide inland plains. Volcanic mountains rise on most of the country's larger islands, and many of the volcanoes are active. The highest mountain, Mount Apo on Mindanao, towers 9,692 feet (2,954 meters) above sea level. Violent earthquakes occur frequently.

The Philippines has many fine bays and harbors. Large lakes include Laguna de Bay on Luzon and Lake Sultan Alonto on Mindanao. Most of the rivers flow only in the rainy season, from June to February. The Philippine Trench, one of the deepest spots in all the oceans, is off the northeast coast of Mindanao. It is 34,578 feet (10,539 meters) below the surface of the Pacific.

A wide variety of plants and animals live in the Philippines. Banyan and palm trees grow in the forests. Thick groves of bamboo and about 9,000 other kinds of flowering plants grow throughout the islands. Wild animals of the Philippines include crocodiles, monkeys, snakes, and many species of tropical birds. Tarsiers—small mammals with owllike eyes—live only in the Philippine and the East Indies. The chief domestic animal in the Philippines is the carabao, a type of water buffalo that farmers use to pull plows and do other heavy work.

The main islands. The Philippine Islands extend 1,152 miles (1,854 kilometers) from north to south and 688 miles (1,107 kilometers) from east to west. The islands form three groups. The northern group consists two large islands, Luzon and Mindoro. The central group, called the Visayan Islands, is made up of about 7,000 islands. The southern group consists of Mindana and the Sulu Archipelago, a group of about 400 islands that extend south and west toward Borneo. This sectior describes the 11 largest islands of the Philippines. The islands are listed in order of size.

Luzon, *loo ZAHN* (area 40,420 square miles, or 104,6 square kilometers), in the northern group, is the most important island. Manila lies on the southwest coast. Luzon produces most of the nation's rice and tobacco. It also has deposits of copper, gold, and other minerals.

Mindanao, *MIHN dah NOW* or *MIHN dah NAH oh* (area 36,537 square miles, or 94,630 square kilometers), is at the southeastern end of the Philippines. The country's highest mountains, including some active volcanoes, a on this island. Mindanao is one of the world's leading producers of *abacá* (Manila hemp). The leaves of the abacá plant contain a strong fiber, which the Filipinos

use in making rope. Fruit plantations cover vast stretches of land.

Samar, *SAH mahr* (area 5,050 square miles, or 13,080 square kilometers), lies in the Visayas. Farmers on the island grow abacá, coconuts, rice, and corn. Industrial development on Samar has caused serious ecological problems. Many of its forests have been cut back, and copper mining and manufacturing have polluted its rivers and streams.

Negros, *NEH grohs* or *NAY grohs* (area 4,905 square miles, or 12,705 square kilometers), in the Visayas, produces sugar and tobacco. Volcanic lava helps fertilize the soil.

Palawan, *pah LAH wahn* (area 4,550 square miles, or 11,785 square kilometers), lies west of the Visayas. Much of Palawan consists of forested hills, but the forests have been rapidly cut back. The people on Palawan raise corn, rice, and vegetables on hillside farms.

Panay, *pah NY* (area 4,446 square miles, or 11,515 square kilometers), in the Visayas, grows coconuts and sugar cane. The Iloilo Plain, in southeastern Panay, is one of the country's most fertile, thickly populated areas.

Mindoro, *mihn DOHR oh* (area 3,759 square miles, or 9,735 square kilometers), is in the northern group. Mindoro produces coconuts, rice, sugar cane, and Philippine mahogany.

Cebu, *seh BOO* or *say BOO* (area 1,707 square miles or 4,422 square kilometers), in the Visayas, is the most densely populated island. It produces corn, rice, sugar cane, tobacco, and coconuts. Its chief city, Cebu City, i a busy port.

Bohol, *boh HAWL* (area 1,492 square miles, or 3,865 square kilometers), lies in the Visayas. The people on this thickly populated island raise corn, rice, coconuts, and abacá.

Masbate, *mahs BAH teh* or *mahs BAH tuh* (area 1,26 square miles, or 3,269 square kilometers), in the Visay is a chief gold-mining area. Scattered farmlands on the island produce coconuts, rice, corn, and sugar cane.

Climate. The Philippines has a hot, humid climate. During the hottest months, from March to May, tempe atures may reach 100 °F. (38 °C). The weather cools off during the rainy season, which lasts from June to Febr ary, but the temperature seldom falls below 70 °F (21 ° Manila has an average temperature of 75 °F (24 °C) in January and 82 °F (28 °C) in May.

Rainfall in the Philippines averages 100 inches (250 centimeters) a year, with some areas receiving up to 1 inches (457 centimeters). The lowlands have less rain than the uplands because the mountains block winds that carry rain-bearing clouds from the ocean. About f typhoons strike the Philippines yearly, causing proper damage and loss of life.

Economy

In the late 1900's and early 2000's, the Philippine eco omy grew less rapidly than the economies of many ot er Asian countries. Unemployment and underemploy ment have been persistent problems. About 20 perce of households in urban areas and almost 50 percent o households in rural areas live below the poverty line.

About 40 percent of Philippine workers make their ing in agriculture, forestry, or fishing. About 45 perce work in service industries, which include education, government, medicine, trade, transportation, commu cation, and financial services. About 15 percent work i manufacturing, construction, and mining.

Agriculture. Filipinos farm only about 35 percent the nation's land. But they produce most of the food f the entire population. Farmers grow rice and corn on about two-thirds of the cultivated land. Other leading food crops include sweet potatoes and *cassava* (a starchy root). Bananas, coconuts, mangoes, pineapple and sugar cane are raised for local use and for export Farmers also raise abacá, hogs, poultry, and tobacco.

Many of the farmers rent land and pay the owner a share of the crop. Most farms lie on lowlands, but far ers also raise crops on hillsides and mountain slopes.

Forestry. Forests cover about one-third of the land the Philippines. More than 3,000 kinds of trees grow i the islands. About 90 percent of the lumber comes fr several related *dipterocarp* trees called Philippine ma hoganies. Mangroves and pines also yield lumber. Th kapok tree produces a fiber, also called kapok, used i making insulation, mattresses, and upholstery. Bamb

rows throughout the islands. Filipinos use the stiff, holıw stems of this plant in building houses and in making askets, furniture, and other items.

Mining. Minerals from rich deposits make up a large art of the Philippines' exports. Copper, the leading minral, occurs mostly on Luzon, Cebu, Negros, and Samar. ırge gold mines operate in northern Luzon. The couny also has deposits of chromite, coal, iron ore, limeone, manganese, nickel, silver, and zinc.

Fishing industry. Anchovies, mackerel, sardines, :ad, tuna, and other fishes are caught in the waters surounding the Philippines. Crabs and shrimp also live in e island waters. Near the southern islands, divers gath- sponges and certain shellfish, including clams and ysters, from which mother-of-pearl is obtained. Milkšh, shrimp, and tilapia are raised in ponds built along e ocean shores and near the mouths of rivers.

e port of Manila is the busiest Philippine port. The nation dends heavily on ships for transportation and trade.

Manufacturing. The principal industries of the Philippines produce cement, chemicals, cigars, clothing, foods and beverages, refined metals and petroleum, sugar, textiles, and wood products. Many companies operate in *export-processing zones,* where businesses can import foreign goods without paying import taxes. Factories in these areas produce such items as electronic equipment, clothing, shoes, and furniture.

Foreign trade. The Philippines cannot produce everything it needs, and so it depends heavily on foreign trade. The nation's chief imports include chemicals, machinery, and petroleum. It trades mainly with Japan and the United States. Electronic equipment and clothing are the Philippines' most valuable exports. The country also exports bananas, coconut products, copper, gold, lumber, pineapples, and sugar.

Transportation. The Philippines has an extensive network of roads. In most cities, brightly decorated vehicles called *jeepneys* serve as shared taxis. They pick up as many passengers as can be crammed in. Buses and jeepneys provide most local transportation in the islands. The Philippines has an average of about 1 automobile for every 80 people. The nation's railroads operate largely on Luzon. The Manila area has an elevated light rail rapid transit system. The government plans to extend the rail lines to ease traffic jams.

Ships and airplanes carry passengers and cargo from one island to another. Manila is the country's busiest port. Other leading ports include Cebu City and Davao. Manila has a major international airport.

Communication. The Philippines has about 20 daily newspapers. Most are published in English, and some are printed in Filipino, Chinese, or other languages. Among the largest newspapers are *Bulletin Today* and *The Times Journal,* both printed in Manila. Almost two-thirds of urban households and about one-quarter of rural households own a television set. There are several television networks.

History

Early days. A tribe of Negritos called the Aeta were probably the first people who lived in the Philippines. Anthropologists believe they came to the islands from the Southeast Asian mainland more than 30,000 years ago. About 3000 B.C., groups of people who spoke a language related to Malay began to settle along the coasts of the islands. As newcomers arrived, the earlier settlers moved inland and formed small communities. Each group developed its own culture.

Spanish settlement and rule. In 1521, a Spanish expedition led by Ferdinand Magellan arrived in the Philippines. Magellan was killed in a battle with native warriors several weeks afterward, and his fleet later departed for Spain. Another group of Spanish explorers, led by General Miguel López de Legazpi, claimed the islands for Spain. They established a settlement in the Philippines in 1565. The Spaniards ruled the Philippines from Manila under the Viceroy of Mexico. They divided the land among themselves and employed Filipinos as tenant farmers, laborers, and servants. Spanish priests converted most of the Filipinos to Roman Catholicism.

Revolt against the Spaniards. Spain opened the islands to foreign trade during the 1800's, and the Philippine economy grew rapidly. Wealthy Filipinos began

sending their children to universities in Manila and Europe. After these young people returned home, they began to seek political and social freedom from Spain. An early leader in the freedom movement was José Rizal, a physician. Rizal worked for reform until 1896, when the Spaniards executed him for his activities.

In 1892, Andres Bonifacio, an office clerk, formed a secret revolutionary society called the *Katipunan*. This group tried to overthrow the government in 1896, and Bonifacio was killed in the revolt. Emilio Aguinaldo, a local chief of the Katipunan, became the leader of the revolutionary forces. The colonial authorities promised political reforms if Aguinaldo ended the revolt and left the Philippines. Aguinaldo agreed and sailed to Hong Kong.

The Spanish-American War. The United States declared war on Spain in April 1898. On May 1, in the first important battle of the war, the U.S. fleet destroyed all the Spanish ships in Manila Bay. Two weeks later, Aguinaldo returned to the islands and formed an army. His forces helped the Americans fight the Spaniards, who had broken their promises to Aguinaldo. On June 12, Aguinaldo declared the Philippines independent from Spain. Philippine and American soldiers defeated the Spanish troops in August, and the war in the islands ended. The United States and Spain signed a peace treaty in December 1898. Under the treaty, the United States gained possession of the Philippines and paid Spain $20 million for the islands.

Aguinaldo claimed that the United States had promised to make the Philippines independent immediately. He declared the establishment of the Philippine Republic on Jan. 23, 1899, and his troops began fighting the Americans on February 4. The Americans captured Aguinaldo in March 1901, and the fighting ended about a year later.

American rule. In 1901, the United States set up a colonial government in the Philippines. William Howard Taft, a federal judge who later became president of the United States, served as the first civilian governor. During the period of American rule, the use of English spread rapidly throughout the islands. American businesses made large investments in the Philippines, and the economy became dependent on the United States.

During the early 1900's, the United States began to allow Filipinos to hold positions in the government. In 1935, the Philippines became a commonwealth with its own elected government and a Constitution modeled after that of the United States. Manuel Quezon became the first president of the commonwealth government. The United States retained authority in such areas as foreign affairs and national defense of the Philippines.

Japanese control. On Dec. 7, 1941, Japanese planes bombed Pearl Harbor, a U.S. naval base in Hawaii. The United States entered World War II the next day. On December 10, Japanese troops invaded the Philippines. American and Philippine forces, led by General Douglas MacArthur, fought them until 1942. MacArthur then left the islands, and Lieutenant General Jonathan M. Wainwright took command of his troops. Large numbers of these troops surrendered to the Japanese in April, though Wainwright and a smaller group held out until May. Most of the American and Philippine soldiers were imprisoned. But others escaped to the mountains along with peasants under communist leadership and continued to resist the Japanese throughout the war.

MacArthur returned to the Philippines with additional troops in October 1944 and defeated the Japanese several months later. The war hurt the Philippine economy badly and destroyed most of Manila.

Independence. The United States granted the Philippines complete independence on July 4, 1946. The Republic of the Philippines was established, with Manuel Roxas as president and Manila the capital. In 1948, Quezon City became the official capital, but Manila remained the seat of the government.

During the late 1940's, political problems and poverty caused widespread discontent among the Philippine people. A Communist-led group called the *Hukbong Magpapalayang Bayan* (People's Liberation Army) tried to take over the government. Its members, known as *Huks,* demanded that the government divide the estates of the wealthy landowners into small lots and give the land to poor farmers. The Philippine Army began to fight the Huks in 1949 and, with the support of the United States, defeated them in 1954.

The Philippines also faced economic problems after gaining independence. The United States sent economic aid, but the economy showed little growth. In 1950, the United States gave additional economic aid. In return, the Philippine government agreed to allow the United States to maintain an air force base—Clark Air Base—and a naval base—Subic Bay Naval Station—on Luzon. The economy began to improve as industries built new plants. Trade with other countries increased. Also, farmers began to use modern methods of agriculture. However, much of the nation remained in poverty.

The Marcos era. In 1965, Ferdinand E. Marcos became president of the Philippines. As president, Marcos sponsored a foreign investment law that encouraged foreign firms to establish factories in the Philippines. He was reelected president in 1969.

Philippine Communists renewed their antigovernment activities in the late 1960's and early 1970's. Young Filipinos organized the New People's Army, which attacked military installations. Many Muslims demanded independence for areas with predominantly Muslim populations. Muslim uprisings occurred on several southern islands. Marcos declared martial law in 1972.

1565 Spanish explorers claimed the Philippines for Spain and established a permanent settlement.

1896 The Spaniards executed José Rizal, a leader of the Philippine independence movement. Emilio Aguinaldo led a revolt against the Spaniards.

1898 Aguinaldo declared independence from Spain on June 12. In December, Spain signed a treaty passing control of the Philippines to the United States.

1942-1944 Japan controlled the Philippines.

1946 The Philippines gained independence.

1954 The Philippine Army defeated the Communist-led Huk rebels after a five-year fight.

1972 President Ferdinand E. Marcos declared a state of martial law, which lasted until 1981.

1986 Widespread protests against President Marcos forced him to leave office.

restricted political parties, labor unions, and other oups that opposed the government.

In 1973, Marcos announced a new constitution that ve him the powers of both president and prime minis-r for an unlimited term. In 1976, by presidential de-ee, Manila again became the nation's capital. Marcos ded martial law in January 1981. In June, he was re-ected president in an election widely regarded as ged.

In 1983, Benigno S. Aquino, Jr., Marcos's leading polit-l rival, was assassinated upon his return to the Philip-nes from self-exile in the United States. Followers of uino charged that the government played a role in killing. A short time later, a court tried the chief of ff of the armed forces, 24 other military men, and one ilian for Aquino's murder. The court acquitted all the cused men in 1985. The acquittal was overturned in 86, and a new trial was held. In 1990, 16 military men re convicted and sentenced to life in prison.

Unrest due to political restrictions and declining eco-mic conditions forced Marcos to hold a presidential ction in February 1986. Corazon Aquino, widow of nigno Aquino, became Marcos's chief opponent. The tional Assembly ruled that Marcos won the election. rge numbers of Filipinos, including bishops of the Ro-n Catholic Church, accused Marcos's supporters of ction fraud. When leading military officers staged a bellion, thousands of people in nearly every province monstrated against Marcos. The strength of popular position forced Marcos to leave the country. Corazon uino took over as president.

Recovering democracy. In February 1987, the Fil-inos voted to approve a new constitution, which pro-led that Aquino serve as president until 1992.

The Marcos administration left behind serious eco-mic problems. Officials charged that Marcos, who ed in 1989, had stolen millions of dollars. In addition, country owed billions of dollars to foreign banks.

Aquino faced opposition from Marcos supporters, m members of the military who objected to negotia-ns with Communist guerrillas, and from groups who posed U.S. influence in the Philippines. Members of military tried several times to overthrow Aquino's vernment but failed to do so. In 1992, Fidel V. Ramos, o had served as deputy chief of staff of the armed ces under Marcos and as defense minister under uino, was elected president.

The United States withdrew from Subic Bay val Station.

Muslim rebel groups in the Philippines had been hting for independence since the 1970's. In 1996, the vernment signed a peace agreement with the largest el group, the Moro National Liberation Front. Automobiles covered with volcanic ash lined streets after Mount Pinatubo erupted. Pinatubo, a volcanic mountain on Luzon, erupted in 1991 for the first time in 600 years.

Recent developments. In 1998, Joseph Estrada was elected president. In 2000, Estrada was accused of corruption. He denied the charges and refused to resign, despite widespread protests. The Philippine House of Representatives voted to *impeach* him—to bring charges of wrongdoing against him, which, if proved, would result in his removal from office. The Senate began the trial, but in 2001, before a verdict was reached, Estrada lost the support of most politicians and the armed forces. Amid continued protests, he was forced to step down and was replaced by his vice president, Gloria Macapagal-Arroyo.

In 2001, the government signed a cease-fire with the Moro Islamic Liberation Front. However, the government refused to negotiate with Abu Sayyaf because it used such tactics as kidnapping. James Putzel

Philistines, *FIHL uh steenz* or *fuh LIHS tihnz,* were an ancient people who settled along the coast of Canaan about the same time that the Israelites were entering the land from the east. The Philistines were part of a larger movement known as the Sea Peoples who had fled the Aegean area near the end of the 1200's B.C. The center of the Philistine territory was in and around the cities of Gaza, Ashkelon, Ashdod, Ekron, and Gath. This area corresponds to what is now southwestern Israel. The name *Palestine,* used for this region and nearby areas, comes from the name *Philistine.*

During the 1100's and 1000's, the Philistines and the Israelites fought many battles. The Philistines had learned the art of smelting iron from the Hittites. This gave them a military and economic advantage over the Israelites. Only after the Israelites anointed Saul as their first king about 1029 B.C. did they become strong enough to drive the Philistines back. After David became king of Israel about 1000 B.C., he subdued the Philistines. After about 600 B.C., the Philistines ceased to exist as a distinct people. The word *philistine* today means a person who is indifferent or hostile to the arts. H. Darrell Lance

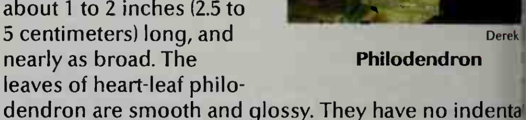
Phillips, Wendell (1811-1884), an orator and reformer, became famous as a supporter of abolition. In Boston in 1837, Phillips delivered an address rebuking those who upheld the mob murder of Elijah P. Lovejoy, an antislavery leader, in Alton, Illinois. Phillips's address became one of the most famous speeches in history for its protest against mob rule. His other well-known speeches include "Burial of John Brown," "Toussaint L'Ouverture," and "The Lost Arts."

Unyielding in his opposition to slavery, Phillips gave up his law practice in 1837 to join William Lloyd Garrison's group of abolitionists. He fought courageously against any individual, institution, or law that he thought prevented abolition. Phillips favored ending slavery even at the cost of breaking up the Union. He severely criticized the administration of President Abraham Lincoln during the American Civil War (1861-1865).



After the war, Phillips held together the American Anti-Slavery Society until the 15th Amendment was passed. This amendment made it illegal to deny the right to vote on the basis of race. Phillips also became interested in improving conditions for laborers. In 1870, the Prohibition and Labor Reform parties nominated him for governor of Massachusetts, and he won almost 15 percent of the vote.

Phillips was born on Nov. 9, 1811, in Boston. He graduated from Harvard University. He died on Feb. 3, 1884 Michael F. Holt

Philodendron, *FIHL uh DEHN druhn,* is the name of many species and varieties of vinelike house plants grown for their attractive foliage. *Philodendron* means *lover of trees.* Many philodendrons are grown on post made of sphagnum moss, bark, and other materials. Th plants produce roots along their stems and will grow poles if the stems are kept moist.

Philodendrons have handsome leaves that are thick and tough. But the leaves vary widely in size and shape on the different species of plants. The common name for some of these plants often suggests the form of their leaves. Among them are the *taper-tip, twice-cut, giant-leaf,* and *tri-leaf* philodendron.

Philodendron

Perhaps the most widely grown is the *heart-leaf* philodendron. This plant bears heart-shaped leaves about 1 to 2 inches (2.5 to 5 centimeters) long, and nearly as broad. The leaves of heart-leaf philodendron are smooth and glossy. They have no indentations along their edges.

Philodendrons are easy to grow as house plants. Th tolerate the changes in light, moisture, and temperatu that are common in most houses. They need little care and do not fall prey to the usual plant pests. They grow best when they are not in direct sunlight. Often philodendrons will grow well in places that are too dark for other plants. They can be grown in almost any kind of soil and will also thrive in water. Theodore R. Dudley

Scientific classification. Philodendrons belong to the aru family, Araceae. The heart-leaf philodendron is *Philodendron cordatum.*

Philosophes, *FIHL uh ZAHFS,* were a group of Frenc philosophers during the Age of Reason, a historical pe riod that extended from the late 1600's to the late 1700 The group included such great philosophers as the Marquis de Condorcet, Denis Diderot, Claude Helvéti Jean-Jacques Rousseau, and Voltaire.

Generally, the philosophes believed in the ideal of progress. They wished to apply science's emphasis on reason to the study of people's moral and social life. T philosophes believed that knowledge could be acquired through experience. They wanted to separate moral doctrines from religious considerations, becaus they believed that moral problems could be solved independently. The philosophes were generally anti-Christian, claiming that Christianity was basically unrea sonable and superstitious. Generally, they opposed th political system in France and argued for reforms. Thu they became forerunners of, and in some cases partic pants in, the French Revolution—which lasted from 17 to 1799 (see **French Revolution**). James Creech

hilosophy is a study that seeks to understand the ysteries of existence and reality. It tries to discover the ature of truth and knowledge and to find what is of bac value and importance in life. It also examines the retionships between humanity and nature and between e individual and society. Philosophy arises out of wonər, curiosity, and the desire to know and understand. hilosophy is thus a form of inquiry—a process of analys, criticism, interpretation, and speculation.

The term *philosophy* cannot be defined precisely beuse the subject is so complex and so controversial. ifferent philosophers have different views of the nare, methods, and range of philosophy. The term *phisophy* itself comes from the Greek *philosophia,* which eans *love of wisdom.* In that sense, wisdom is the ace use of intelligence, not something passive that a erson simply possesses.

The first known Western philosophers lived in the anent Greek world during the early 500's B.C. These early hilosophers tried to discover the basic makeup of ings and the nature of the world and of reality. For anvers to questions about such subjects, people had rgely relied on magic, superstition, religion, tradition, authority. But the Greek philosophers considered ose sources of knowledge unreliable. Instead, they ought answers by thinking and by studying nature.

Philosophy has also had a long history in some non'estern cultures, especially in China and India. But until bout 200 years ago, there was little interchange beveen those philosophies and Western philosophy, iefly because of difficulties of travel and communican. As a result, Western philosophy generally develed independently of Eastern philosophy.

The importance of philosophy

Philosophic thought is an inescapable part of human istence. Almost everyone has been puzzled from time time by such essentially philosophic questions as /hat does life mean?" "Did I have any existence before I as born?" and "Is there life after death?" Most people so have some kind of philosophy in the sense of a pernal outlook on life. Even a person who claims that nsidering philosophic questions is a waste of time is pressing what is important, worthwhile, or valuable. A jection of all philosophy is in itself philosophy.

By studying philosophy, people can clarify what they lieve, and they can be stimulated to think about ultiate questions. A person can study philosophers of the st to discover why they thought as they did and what lue their thoughts may have in one's own life. There e people who simply enjoy reading the great philosoers, especially those who were also great writers.

Philosophy has had enormous influence on our everyy lives. The very language we speak uses classificans derived from philosophy. For example, the classifitions of noun and verb involve the philosophic idea at there is a difference between things and actions. If e ask what the difference is, we are starting a philophic inquiry.

Marcus G. Singer, the contributor of this article, is Emeritus ofessor of Philosophy at the University of Wisconsin-Madison d coeditor of Introductory Readings in Philosophy.

Every institution of society is based on philosophic ideas, whether that institution is the law, government, religion, the family, marriage, industry, business, or education. Philosophic differences have led to the overthrow of governments, drastic changes in laws, and the transformation of entire economic systems. Such changes have occurred because the people involved held certain beliefs about what is important, true, real, and significant and about how life should be ordered.

Systems of education follow a society's philosophic ideas about what children should be taught and for what purposes. Democratic societies stress that people learn to think and make choices for themselves. Nondemocratic societies discourage such activities and want their citizens to surrender their own interests to those of the state. The values and skills taught by the educational system of a society thus reflect the society's philosophic ideas of what is important.

The branches of philosophy

Philosophic inquiry can be made into any subject because philosophy deals with everything in the world and all of knowledge. But traditionally, and for purposes of study, philosophy is divided into five branches, each organized around certain distinctive questions. The branches are (1) metaphysics, (2) epistemology, (3) logic, (4) ethics, and (5) aesthetics. In addition, the philosophy of language became so important during the 1900's that it is often considered another branch of philosophy.

Metaphysics is the study of the fundamental nature of reality and existence and of the essences of things. Metaphysics is itself often divided into two areas—*ontology* and *cosmology.* Ontology is the study of being. Cosmology is the study of the physical universe, or the cosmos, taken as a whole. Cosmology is also the name of the branch of science that studies the organization, history, and future of the universe.

Metaphysics deals with such questions as "What is real?" "What is the distinction between appearance and reality?" "What are the most general principles and concepts by which our experiences can be interpreted and understood?" and "Do we possess free will or are our actions determined by causes over which we have no control?"

Philosophers have developed a number of theories in metaphysics. These theories include *materialism, idealism, mechanism,* and *teleology.* Materialism maintains that only matter has real existence and that feelings, thoughts, and other mental phenomena are produced by the activity of matter. Idealism states that every material thing is an idea or a form of an idea. In idealism, mental phenomena are what is fundamentally important and real. Mechanism maintains that all happenings result from purely mechanical forces, not from purpose, and that it makes no sense to speak of the universe itself as having a purpose. Teleology, on the other hand, states that the universe and everything in it exists and occurs for some purpose.

Epistemology aims to determine the nature, basis, and extent of knowledge. It explores the various ways of knowing, the nature of truth, and the relationships between knowledge and belief. Epistemology asks such questions as "What are the features of genuine knowledge as distinct from what appears to be knowledge?"

"What is truth, and how can we know what is true and what is false?" and "Are there different kinds of knowledge, with different grounds and characteristics?"

Philosophers often distinguish between two kinds of knowledge, *a priori* and *empirical.* We arrive at a priori knowledge by thinking, without independent appeal to experience. For example, we know that there are 60 seconds in a minute by learning the meanings of the terms. In the same way, we know that there are 60 minutes in an hour. From these facts, we can deduce that there are 3,600 seconds in an hour, and we arrive at this conclusion by the operation of thought alone. We acquire empirical knowledge from observation and experience. For example, we know from observation how many keys are on a typewriter and from experience which key will print what letter.

The nature of truth has baffled people since ancient times, partly because people so often use the term *true* for ideas they find congenial and want to believe, and also because people so often disagree about which ideas are true. Philosophers have attempted to define criteria for distinguishing between truth and error. But they disagree about what truth means and how to arrive at true ideas. The *correspondence theory* holds that an idea is true if it corresponds to the facts or reality. The *pragmatic theory* maintains that an idea is true if it works or settles the problem it deals with. The *coherence theory* states that truth is a matter of degree and that an idea is true to the extent to which it *coheres* (fits together) with other ideas that one holds. *Skepticism* claims that knowledge is impossible to attain and that truth is unknowable.

Logic is the study of the principles and methods of reasoning. It explores how we distinguish between good (or sound) reasoning and bad (or unsound) reasoning. An instance of reasoning is called an *argument* or an *inference.* An argument consists of a set of statements called *premises* together with a statement called the *conclusion,* which is supposed to be supported by or derived from the premises. A good argument provides support for its conclusion, and a bad argument does not. Two basic types of reasoning are called *deductive* and *inductive.*

A good deductive argument is said to be *valid*—that is, the conclusion necessarily follows from the premise A deductive argument whose conclusion does not follow necessarily from the premises is said to be *invalid.* The argument "All human beings are mortal, all Greeks are human beings, therefore all Greeks are mortal" is a valid deductive argument. But the argument "All humar beings are mortal, all Greeks are mortal, therefore all Greeks are human beings" is invalid, even though the conclusion is true. On that line of reasoning, one could argue that all dogs, which are also mortal, are human beings.

Deductive reasoning is used to explore the necessar consequences of certain assumptions. Inductive reasoi ing is used to establish matters of fact and the laws of nature and does not aim at being deductively valid. On who reasons that all squirrels like nuts, on the basis th all squirrels so far observed like nuts, is reasoning inductively. The conclusion could be false, even though the premise is true. Nevertheless, the premise provide considerable support for the conclusion.

Ethics concerns human conduct, character, and values. It studies the nature of right and wrong and the di tinction between good and evil. Ethics explores the nature of justice and of a just society, and also one's obligations to oneself, to others, and to society.

Ethics asks such questions as "What makes right actions right and wrong actions wrong?" "What is good and what is bad?" and "What are the proper values of life?" Problems arise in ethics because we often have d ficulty knowing exactly what is the right thing to do. In many cases, our obligations conflict or are vague. In ac dition, people often disagree about whether a particul action or principle is morally right or wrong.

A view called *relativism* maintains that what is right wrong depends on the particular culture concerned. What is right in one society may be wrong in another,

Terms used in philosophy

Aesthetics is the branch of philosophy that studies art and beauty.

Cosmology is the study of the physical universe.

Determinism is the doctrine that all events have causes and occur by necessity.

Dialectic in the philosophy of G. W. F. Hegel is a process of change brought about by the conflict of opposites. This conflict creates a new unity, called a *synthesis.* The synthesis, in turn, comes into conflict with its opposite.

Empiricism is the view that experience is the source and test of knowledge.

Epicureanism is the belief that pleasure should be the goal of human activity but that true pleasure depends on self-control, moderation, and honorable behavior.

Epistemology is the branch of philosophy that studies the nature, basis, and extent of knowledge.

Ethics is the branch of philosophy that studies human conduct and the nature of right and wrong.

Hedonism is the belief that the pleasure is the highest good.

Humanism is a philosophy that stresses the importance of human beings and their nature and place in the universe.

Idealism is the belief that fundamental reality is made up of minds and ideas, not of material objects. Idealists believe th the existence of objects depends on minds and ideas.

Logic is the branch of philosophy that deals with the principle of reasoning.

Materialism is a belief that only matter has real existence and that mental phenomena are produced by the activity of matter.

Metaphysics is the branch of philosophy that seeks to understand the nature of being and reality.

Pragmatism is a philosophy that tests the truth and value of ideas by their practical consequences.

Rationalism is the theory that knowledge can be derived fror reason by itself, independent of the senses.

Realism is the doctrine that things exist in and of themselves, independent of ideas that people may have about them.

Skepticism is a philosophy that claims we can never have rea knowledge of anything.

Utilitarianism is the belief that human conduct should be based on what produces the greatest good for the greatest number of people.

s view argues, and so no basic standards exist by ich a culture may be judged right or wrong. *Objectiv-* n claims that there are objective standards of right d wrong which can be discovered and which apply to eryone. *Subjectivism* states that all moral standards subjective matters of taste or opinion.

Aesthetics deals with the creation and principles of and beauty. It also studies our thoughts, feelings, and itudes when we see, hear, or read something beauti-. Something beautiful may be a work of art, such as a inting, symphony, or poem, or it may be a sunset or ier natural phenomenon. In addition, aesthetics inves-ates the experience of engaging in such activities as inting, dancing, acting, and playing.

Aesthetics is sometimes identified with the philoso-y of art, which deals with the nature of art, the proc- of artistic creation, the nature of the aesthetic experi-ce, and the principles of criticism. But aesthetics has der application. It involves both works of art created human beings and the beauty found in nature.

Aesthetics relates to ethics and political philosophy en we ask questions about what role art and beauty ould play in society and in the life of the individual. ch questions include "How can people's taste in the s be improved?" "How should the arts be taught in the iools?" and "Do governments have the right to restrict istic expression?"

The philosophy of language has become especially portant in recent times. Some philosophers claim that philosophic questions arise out of linguistic prob-ns. Others claim that all philosophic questions are re- questions about language. One key question is hat is language?" But there are also questions about relationships between language and thought and ween language and the world, as well as questions out the nature of meaning and of definition.

The question has been raised whether there can be a ically perfect language that would reflect in its cate-ies the essential characteristics of the world. This estion raises questions about the adequacy of ordi-y language as a philosophic tool. All such questions ong to the philosophy of language, which has essen- connections with other branches of philosophy.

Philosophy and other fields

One peculiarity of philosophy is that the question hat is philosophy?" is itself a question of philosophy. the question "What is art?" is not a question of art. question is philosophic. The same is true of such estions as "What is history?" and "What is law?" Each is uestion of philosophy. Such questions are basic to philosophy of education, the philosophy of history, philosophy of law, and other "philosophy of" fields. h of these fields attempts to determine the founda-is, fundamental categories, and methods of a particu- institution or area of study. A strong relationship refore exists between philosophy and other fields of nan activity. This relationship can be seen by examin- two fields: (1) philosophy and science and (2) philos-iy and religion.

Philosophy and science. Science studies natural nomena and the phenomena of society. It does not ly itself. When science does reflect on itself, it be-ies the philosophy of science and examines a number of philosophic questions. These questions include "What is science?" "What is scientific method?" "Does scientific truth provide us with the truth about the universe and reality?" and "What is the value of science?"

Philosophy has given birth to several major fields of scientific study. Until the 1700's, no distinction was made between science and philosophy. For example, physics was called *natural philosophy.* Psychology was part of what was called *moral philosophy.* In the early 1800's, sociology and linguistics separated from philosophy and became distinct areas of study. Logic has always been considered a branch of philosophy. However, logic has now developed to the point where it is also a branch of mathematics, which is a basic science.

Philosophy and science differ in many respects. For example, science has attained definite and tested knowledge of many matters and has thus resolved disagreement about those matters. Philosophy has not. As a result, controversy has always been characteristic of philosophy. Science and philosophy do share one significant goal. Both seek to discover the truth—to answer questions, solve problems, and satisfy curiosity. In the process, both science and philosophy provoke further questions and problems, with each solution bringing more questions and problems.

Philosophy and religion. Historically, philosophy originated in religious questions. These questions concerned the nature and purpose of life and death and the relationship of humanity to superhuman powers or a divine creator. Every society has some form of religion. Most people acquire their religion from their society as they acquire their language. Philosophy inquires into the essence of things, and inquiry into the essence of religion is a philosophic inquiry.

Religious ideas generated some of the earliest philosophic speculations about the nature of life and the universe. The speculations often centered on the idea of a supernatural or superpowerful being who created the universe and who governs it according to unchangeable laws and gives it purpose. Western philosophic tradition has paid much attention to the possibility of demonstrating the existence of God.

The chief goal of some philosophers is not understanding and knowledge. Instead, they try to help people endure the pain, anxiety, and suffering of earthly existence. Such philosophers attempt to make philosophic reflection on the nature and purpose of life perform the function of religion.

Oriental philosophy

There are two main traditions in Oriental philosophy, Chinese and Indian. Both philosophies are basically religious and ethical in origin and character. They are removed from any interest in science.

Traditionally, Chinese philosophy has been largely practical, humanistic, and social in its aims. It developed as a means of bringing about improvements in society and politics. Traditionally, philosophy in India has been chiefly mystical rather than political. It has been dominated by reliance on certain sacred texts, called Vedas, which are considered inspired and true and therefore subject only for commentary and not for criticism. Much of Indian philosophy has emphasized withdrawal from everyday life into the life of the spirit. Chinese philoso-

phy typically called for efforts to participate in the life of the state in order to improve worldly conditions.

Chinese philosophy as we know it started in the 500's B.C. with the philosopher Confucius. His philosophy, called Confucianism, was the official philosophy of China for centuries, though it was reinterpreted by different generations. Confucianism aimed to help people live better and more rewarding lives by discipline and by instruction in the proper goals of life. Candidates for government positions had to pass examinations on Confucian thought, and Confucianism formed the basis for government decisions. No other civilization has placed such emphasis on philosophy.

Other philosophic traditions in China were Taoism, Mohism, and realism. Beginning in the 1100's, a movement known as Neo-Confucianism incorporated elements of all these doctrines.

We do not know exactly when Indian philosophy began. In India, philosophic thought was intermingled with religion, and most Indian philosophic thought has been religious in character and aim. Philosophic commentaries on sacred texts emerge during the 500's B.C. The Indian word for these studies is *darshana,* which means *vision* or *seeing.* It corresponds to what the ancient Greeks called *philosophia.*

In India, as in China, people conceived of philosophy as a way of life, not as a mere intellectual activity. The main aim of Indian philosophy was freedom from the suffering and tension caused by the body and the senses and by attachment to worldly things. The main philosophies developed in India were Hinduism and Buddhism, which were also religions. Yet some Indian philosophers did develop a complex system of logic and carried on investigations in epistemology. Some Indian philosophic ideas have been influential in the West. One such idea is *reincarnation,* the belief that the human soul is successively reborn in new bodies.

The history of Western philosophy

The history of Western philosophy is commonly divided into three periods—ancient, medieval, and modern. The period of ancient philosophy extended from about 600 B.C. to about the A.D. 400's. Medieval philosophy lasted from the 400's to the 1600's. Modern philosophy covers the period from the 1600's to the present.

Ancient philosophy was almost entirely Greek. The greatest philosophers of the ancient world were three Greeks of the 400's and 300's B.C.—Socrates, Plato, and Aristotle. Their philosophy influenced all later Western culture. Our ideas in the fields of metaphysics, science, logic, and ethics originated from their thought. A number of distinctive schools of philosophy also flourished in ancient Greece.

The pre-Socratics were the first Greek philosophers. Their name comes from the fact that most of them lived before the birth of Socrates, which was about 469 B.C. The pre-Socratic philosophers were mainly interested in the nature and source of the universe and the nature of reality. They wanted to identify the fundamental substance that they thought underlay all phenomena, and in terms of which all phenomena could be explained.

Unlike most other people of their time, the pre-Socratic philosophers did not believe that gods or supernatural forces caused natural events. Instead, they sought a natural explanation for natural phenomena. T philosophers saw the universe as a set of connected a unified phenomena for which thought could find an e planation. They gave many different and conflicting an swers to basic philosophic questions. However, the im portance of the pre-Socratics lies not in the truth of th answers but in the fact that they examined the questio in the first place. They had no philosophic tradition to work from, but their ideas provided a tradition for all later philosophers.

Socrates left no writings, though he was constantly engaged in philosophic discussion. Our knowledge o his ideas and methods comes mainly from dialogues written by his pupil Plato. In most of the dialogues, Sc rates appears as the main character, who leads and de velops the process of inquiry.

Socrates lived in Athens and taught in the streets, market place, and gymnasiums. He taught by a questio and-answer method. Socrates tried to get a definition precise view of some abstract idea, such as knowledg virtue, justice, or wisdom. He would use close, sharp questioning, constantly asking "What do you mean?" a "How do you know?" This procedure, called the *Socra method,* became the model for philosophic methods that emphasize debate and discussion.

Socrates wanted to replace vague opinions with cle ideas. He often questioned important Athenians and e posed their empty claims to knowledge and wisdom. This practice made him many enemies, and he was pu to death as a danger to the state. He thus became a sy bol of the philosopher who pursued an argument whe ever it led to arrive at the truth, no matter what the co

Plato believed that we cannot gain knowledge of things through our senses because the objects of sen perception are fleeting and constantly changing. Plato stated that we can have genuine knowledge only of changeless things, such as truth, beauty, and goodnes which are known by the mind. He called such things *ideas* or *forms.*

Plato taught that only ideas are real and that all othe things only reflect ideas. This view became known as *idealism.* According to Plato, the most important idea the idea of good. Knowledge of good is the object of inquiry, a goal to which all other things are subordina Plato stated that the best life is one of contemplation o eternal truths. However, he believed people who have attained this state must return to the world of everyda life and use their skills and knowledge to serve huma ity. Plato also believed that the soul is immortal and th only the body perishes at death. His ideas contributed views about the body, soul, and eternal things later de veloped in Christian theology.

Aristotle, Plato's greatest pupil, wrote about almost every known subject of his day. He invented the idea o a science and of separate sciences, each having distin principles and dealing with different subject matter. H wrote on such topics as physics, astronomy, psychology, biology, physiology, and anatomy. Aristotle also i vestigated what he called "first philosophy," later know as *metaphysics.*

Aristotle created the earliest philosophic system. In his philosophy, all branches of inquiry and knowledge are parts of some overall system and connected by th same concepts and principles. Aristotle believed that

ngs in nature have some purpose. According to his ilosophy, the nature of each thing is determined by its rpose, and all things seek to fulfill their natures by rrying out these purposes.

Aristotle's basic method of inquiry consisted of start- g from what we know or think we know and then ask- g how, what, and why. In his metaphysics, he devel- ed the idea of a *first cause,* which was not itself used by anything, as the ultimate explanation of exist- ce. Christian theologians later adopted this idea as a sic argument for the existence of God. Aristotle taught at everyone aims at some good. He said that happi- ss does not lie in pleasure but in virtuous activity. By tuous activity, he meant behaving according to a *ean* between extremes. For example, courage is the ean between the extremes of cowardice and foolhar- ness. The highest happiness of all, Aristotle believed, as the contemplative use of the mind.

Stoic philosophy and Epicureanism were the two ain schools of Greek philosophy that emerged after e death of Aristotle in 322 B.C. Both schools taught that e purpose of knowing is to enable a person to lead e best and most contented life.

Stoic philosophy was founded by Zeno of Citium. He ught that people should spend their lives trying to cul- ate virtue, the greatest good. The Stoics believed in ict *determinism*—the idea that all things are fated to . Therefore, they said, a wise and virtuous person ac- pts and makes the best of what cannot be changed. oicism spread to Rome. There, the chief Stoics in- uded the statesman Marcus Tullius Cicero, the em- ror Marcus Aurelius, and the teacher Epictetus.

Epicureanism was founded by Epicurus. Epicurus sed his philosophy on *hedonism*—the idea that the ly good in life is pleasure. However, Epicurus taught at not all pleasures are good. The only good pleasures e calm and moderate ones because extreme pleasures uld lead to pain. The highest pleasures, Epicurus said, e physical health and peace of mind, two kinds of free- m from pain.

Skepticism was a school of philosophy founded by rrho of Elis about the same time that Stoic philosophy d Epicureanism flourished. Pyrrho taught that we can ow nothing. Our senses, he said, deceive us and pro- de no accurate knowledge of the way things are. Thus, claims to knowledge are false. Because we can know thing, in this view, we should treat all things with in- fference and make no judgments.

Neoplatonism was a revived version of some of ato's ideas as adapted by Plotinus, a philosopher who ay have been born in Egypt in the A.D. 200's. Neoplato- sm tried to guide the individual toward a unity—a eness—with God, which is a state of blessedness. Plo- us believed that the human soul yearns for reunion th God, which it can achieve only in mystical experi- ce. Neoplatonism provided the bridge between Greek ilosophy and early Christian philosophy. It inspired e idea that important truths can be learned only rough faith and God's influence, not by reason.

Medieval philosophy. During the Middle Ages, estern philosophy developed more as a part of Chris- n theology than as an independent branch of inquiry. e philosophy of Greece and Rome survived only in its fluence on religious thought.

Saint Augustine was the greatest philosopher of the early Middle Ages. In a book titled *The City of God* (early 400's), Augustine interpreted human history as a conflict between faithful Christians living in the city of God and pagans and heretics living in the city of the world. Augustine wrote that the people of the city of God will gain eternal salvation, but the people in the city of the world will receive eternal punishment. The book weakened the belief in the pagan religion of Rome and helped further the spread of Christianity.

A system of thought called *scholasticism* dominated medieval philosophy from about the 1100's to the 1400's. The term *scholasticism* refers to the method of philosophic investigation used by teachers of philosophy and theology in the newly developing universities of western Europe. The teachers were called *scholastics.* The scholastic method consisted in precise analysis of concepts with subtle distinctions between different senses of these concepts. The scholastics used deductive reasoning from principles established by their method to provide solutions to problems.

Scholasticism was basically generated by the translation of Aristotle's works into Latin, the language of the medieval Christian church. These works presented medieval thinkers with the problem of reconciling Aristotle's great body of philosophic thought with the Bible and Christian doctrine. The most famous scholastic was Saint Thomas Aquinas. His philosophy combined Aristotle's thought with theology, and it eventually became the official philosophy of the Roman Catholic Church.

The great contributions of the scholastics to philosophy included major development of the philosophy of language. The scholastics studied how features of language can affect our understanding of the world. They also emphasized the importance of logic to philosophic inquiry.

Modern philosophy. A great cultural movement in Europe called the Renaissance overlapped the end of the Middle Ages and formed a transition between medieval and modern philosophy. The Renaissance began in Italy and lasted from about 1300 to about 1600. It was a time of intellectual reawakening stemming from the rediscovery of ancient Greek and Roman culture. During the Renaissance, major advances occurred in such sciences as astronomy, physics, and mathematics. Scholars called *humanists* stressed the importance of human beings and the study of classical literature as a guide to understanding life. Emphasis on science and on humanism led to changes in the aims and techniques of philosophic inquiry. Scholasticism declined, and philosophy was freed of its ties to medieval theology.

One of the earliest philosophers to support the scientific method was Francis Bacon of England. Most historians consider Bacon and René Descartes of France to be the founders of modern philosophy. Bacon wrote two influential works, *The Advancement of Learning* (1605) and *Novum Organum* (1620). He stated that knowledge was power and that knowledge could be obtained only by the inductive method of investigation. Bacon imagined a new world of culture and leisure that could be gained by inquiry into the laws and processes of nature. In describing this world, he anticipated the effects of advances in science, engineering, and technology.

Rationalism was a philosophic outlook that arose in

Saint Augustine was the most important philosopher of the early Middle Ages. In the A.D. 400's, he developed theories on sin, grace, and salvation that greatly influenced Christian doctrine.

the 1600's. The basis of rationalism is that reason is su
rior to experience as a source of knowledge and that
validity of sense perception must be proved from mo
certain principles. The rationalists tried to determine t
nature of the world and of reality by deduction from premises themselves established as certain *a priori.* They also stressed the importance of mathematical pr
cedures. The leading rationalists were René Descartes
Baruch Spinoza, and Gottfried Wilhelm Leibniz.

Descartes was a mathematician as well as a philoso
pher. He invented analytic geometry. Descartes's basic idea was to establish a secure foundation for the sciences, a foundation of the sort he had found for math
matics. He was thus much concerned with the foundations of knowledge, and he started philosophy on its persistent consideration of epistemological problems. Descartes was a *mechanist*—that is, he regarded all physical phenomena as connected mechanically by la
of cause and effect. Descartes's philosophy generated the problem of how mind and matter are related.

Spinoza constructed a system of philosophy on the model of geometry. He attempted to derive philosoph
conclusions from a few central *axioms* (supposedly se
evident truths) and definitions. Spinoza did not view G
as some superhuman being who created the universe
He identified God with the universe. Spinoza was also
mechanist, regarding everything in the universe as determined. Spinoza's main aim was ethical. He wanted t
show how people could be free, could lead reasonabl
and thus satisfying lives, in a deterministic world.

Leibniz believed that the actual world is only one of many possible worlds. He tried to show how the actua
world is the best of all possible worlds in an effort to justify the ways of God to humanity. Thus, he attempte
to solve the problem of how a perfect and all-powerfu
God could have created a world filled with so much su
fering and evil. Leibniz and Sir Isaac Newton, an Englis
scientist, independently developed calculus. Leibniz's work in mathematics anticipated the development of *symbolic logic*—the use of mathematical symbols and
operations to solve problems in logic.

Empiricism emphasizes the importance of experien
and sense perception as the source and basis of know
edge. The first great empiricist was John Locke of England in the 1600's. George Berkeley of Ireland and Davi
Hume of Scotland further developed empiricism in th
1700's.

Locke tried to determine the origin, extent, and certainty of human knowledge in *An Essay Concerning Hu
man Understanding* (1690). Locke argued that there are no *innate* ideas—that is, ideas people are born with. He believed that when a person is born, the mind is like a blank piece of paper. Experience is therefore the sourc
of all ideas and all knowledge.

Berkeley dealt with the question "If whatever a huma
being knows is only an idea, how can one be sure that there is anything in the world corresponding to that idea?" Berkeley answered that "to be is to be perceived
No object exists, he said, unless it is perceived by som
mind. Material objects are ideas in the mind and have no independent existence.

Hume extended the theories of Locke and Berkeley
a consistent skepticism about almost everything. He maintained that everything in the mind consists of im-

ressions and ideas, with ideas coming from impressions. Every idea can be traced to and tested by some arlier impression. According to Hume, we must be ble to determine from what impression we derived an ea for that idea to have meaning. An apparent idea that annot be traced to an impression must be meaningless. ume also raised the question of how can we know that e future will be like the past—that the laws of nature ill continue to operate as they have. He claimed that e can only know that events have followed certain patrns in the past. We cannot therefore be certain that ents will continue to follow those patterns.

The Age of Reason was a period of great intellectual tivity that began in the 1600's and lasted until the late 700's. The period is also called the Enlightenment. hilosophers of the Age of Reason stressed the use of ason, as opposed to the reliance on authority and riptural revelation. For them, reason provided means attaining the truth about the world and of ordering uman society to assure human well-being. The leading hilosophers included Descartes, Locke, Berkeley, and ume. They also included Jean-Jacques Rousseau, oltaire, Denis Diderot, and other members of a group French philosophers called the *philosophes.*

Locke's philosophic ideas were characteristic of the ge of Reason. Locke sought to determine the limits of uman understanding and to discover what can be nown within those limits that will serve as a guide to e and conduct. He tried to show that people should e by the principles of toleration, liberty, and natural ghts. His *Two Treatises of Government* (1690) provided e philosophic base for the Revolutionary War in merica and the French Revolution in the late 1700's.

The philosophy of Immanuel Kant, a great German hilosopher of the late 1700's, became the foundation r nearly all later developments in philosophy. Kant's philosophy is called *critical philosophy* or *transcendental philosophy.* Kant was stimulated by the skeptical philosophy of Hume to try to bring about a synthesis of rationalism and empiricism. In his *Critique of Pure Reason* (1781), Kant tried to provide a critical account of the powers and limits of human reason, to determine what is knowable and what is unknowable. Kant concluded that reason can provide knowledge only of things as they appear to us, never of things as they are in themselves. Kant believed that the mind plays an active role in knowing and is not a mere recorder of facts presented by the senses. The mind does this through basic categories or forms of understanding, which are independent of experience and without which our experience would not make sense. Through such categories and the operations of the mind, working on sense experience, we can have knowledge, but only of things that can be experienced.

Kant criticized the traditional arguments for the existence of God. He argued that they are all in error because they make claims that go beyond the possibility of experience and thus go beyond the powers of human reason. In his *Critique of Practical Reason* (1788), Kant argued that *practical reason* (reason applied to practice) can show us how we ought to act and also provides a practical reason for believing in God, though not a proof that God exists.

Philosophy in the 1800's. Kant's philosophy stimulated various systems of thought in the 1800's, such as those of G. W. F. Hegel and Karl Marx of Germany. Hegel developed a theory of historical change called *dialectic,* in which the conflict of opposites results in the creation of a new unity and then its opposite. Hegel's theory was transformed by Marx into *dialectical materialism.* Marx believed that only material things are real. He stated that all ideas are built on an economic base. He believed that

the dialectic of conflict between capitalists and industrial workers will lead to the establishment of communism, which he called *socialism,* as an economic and political system.

Friedrich Nietzsche, a German philosopher, was an atheist who proclaimed in *Thus Spake Zarathustra* (1883-1885) that "God is dead." Nietzsche meant that the idea of God had lost the power to motivate and discipline large masses of people. He believed that people would have to look to some other idea to guide their lives. Nietzsche predicted the evolution of the *superman,* who would be beyond the weakness of human beings and beyond the merely human appeals to morality. He regarded such appeals as appeals to weakness, not strength. He felt that all behavior is based on the *will to power*—the desire of people to control others and their own passions. The superman would develop a new kind of perfection and excellence through the capacity to realize the will to power through strength, rather than weakness.

The dominant philosophy in England during the 1800's was *utilitarianism,* developed by Jeremy Bentham and John Stuart Mill. The utilitarians maintained that the greatest happiness for the greatest number of people is the test of right and wrong. They argued that all existing social institutions, especially law and government, must be transformed to satisfy the test of greatest happiness. In *The Subjection of Women* (1869), Mill wrote that the legal subordination of women to men ought to be replaced by "a principle of perfect equality." That idea was revolutionary in Mill's time.

Philosophy in the 1900's saw five main movements predominate. Two of these movements, *existentialism* and *phenomenology,* had their greatest influence in the countries on the mainland of western Europe. The three other movements, *pragmatism, logical positivism,* and *philosophical analysis,* were influential chiefly in the United States and the United Kingdom.

Existentialism became influential in the mid-1900's. World War II (1939-1945) gave rise to widespread feelings of despair and of separation from the established order. These feelings led to the idea that people have t create their own values in a world in which traditional values no longer govern. Existentialism insists that choi es have to be made arbitrarily by individuals, who thus create themselves, because there are no objective standards to determine choice. The most famous of the existentialist philosophers is the French author Jean-Pa Sartre.

Phenomenology was developed by the German philosopher Edmund Husserl. Husserl conceived the task of phenomenology, hence the task of philosophy, as describing phenomena—the objects of experience—accurately and independently of all assumptions derive from science. He thought that this activity would provid philosophic knowledge of reality.

Pragmatism, represented in the 1900's by William James and John Dewey of the United States, maintains knowledge is subordinate to action. The meaning and truth of ideas are determined by their relation to practice.

Logical positivism, developed in Vienna, Austria, in the 1920's, believes philosophy should analyze the logic of the language of science. It regards science as the onl source of knowledge and claims metaphysics is meaningless. It bases this claim on the principle of *verifiability,* by which a statement is meaningful only if it can be verified by sense experience.

Philosophical analysis generally tries to solve philosophic problems through analysis of language or concepts. Some versions of this philosophy attempt to sho that traditional philosophic problems *dissolve*—that is, disappear—on proper analysis of the terms in which they are expressed. Other versions use linguistic analysis to throw light on, not dissolve, traditional philosoph ic problems. The most influential philosophers practicing philosophic analysis have been Bertrand Russell of England and Ludwig Wittgenstein, who was born in Austria but studied and taught in England.

Phlebitis, *flih BY tihs,* is an inflammation of a vein. Phlebitis can develop in any part of the body, but it most commonly occurs in the legs. The condition usually produces tenderness, swelling, redness, and pain in the area of the vein. It may lead to *thrombophlebitis*—that is, the formation of a blood clot along the lining of the inflamed vein. Serious problems can result if the blood clot breaks loose and travels through the bloodstream. The clot may become stuck and create an *embolism* (blockage of a blood vessel). An embolism that occurs in the heart or lungs can be fatal (see **Embolism**).

Most cases of phlebitis are caused by an injury or by an infection of a vein. Phlebitis also may result from poor circulation in the veins due to prolonged bed rest, pregnancy, extreme fatness, or heart failure.

In treating phlebitis of the legs, physicians advise elevation of the affected limb to reduce inflammation. The patient should wear an elastic support stocking when walking. In severe cases of phlebitis, bed rest is required to prevent clots from breaking loose. Drugs called *anticoagulants* may be prescribed to thin the patient's blood and prevent clotting. In some cases, surgery may be necessary. Wilbert S. Aronow

Phlox, *flahks,* is the name of a group of garden plants with brilliantly colored blossoms. One common species, the *annual phlox* or *Drummond phlox,* is native to Texas. Its flowers range in color from white to red or purple and grow in clusters at the top of the stem. The leaves may be long and narrow or egg-shaped. The plant measures 6 to 18 inches (15 to 46 centimeters) high. The *wild sweet William* is a phlox native to the eastern United States. It has white or pink to purple flowers and may grow 5 feet (1.5 meters) high. The *blue phlox* grows in forests from Quebec to Alabama. It may grow 18 inches high and has bluish or pale lilac flowers. James S. Miller

Scientific classification. Phlox plants belong to the phlox family, Polemoniaceae. The annual phlox is *Phlox drummondii.*

Phnom Penh, *nawm pehn,* is the capital of Cambodia. It lies in the south-central part of the country, where the Tonle Sap and Bassac rivers join the Mekong River. For location, see **Cambodia** (map). Phnom Penh serves as Cambodia's trading and industrial center. The city's products include cigarettes, rubber, and textiles.

Phnom Penh was founded in the 1400's and became the permanent capital in 1867. In 1970, the Vietnam War between Communists and non-Communists spread to Cambodia. A Cambodian Communist group called the Khmer Rouge gained control of the country in 1975. At that time, Phnom Penh had about 2 million people. The Khmer Rouge forced most of the people out of the city

to work in rural areas. The population fell to an estimated 20,000 people. In 1979, Vietnamese troops and a Cambodian Communist group overthrew the Khmer Rouge and took control of Phnom Penh. People then began returning to the city, and the population grew to an estimated 800,000 by the early 1990's.

Phobia, *FOH bee uh,* is a persistent, strong fear of a certain object or situation. Common phobias include fear of crowds, darkness, heights, and such animals as cats, snakes, or spiders. Phobic individuals may spend much time worrying about their fears and may be too frightened to carry out normal activities. Psychologists and psychiatrists classify phobias as an *anxiety disorder,* a mild psychological problem.

Many phobias have special names. The fear of heights is called *acrophobia. Agoraphobia* is the dread of open spaces, and *claustrophobia* is the fear of small places or of being closed in. *Ailurophobia* is the fear of cats, *ophidiophobia* the fear of snakes, and *arachnophobia* the fear of spiders. Other phobias include *hydrophobia* (fear of water), *mysophobia* (fear of dirt or germs), and *xenophobia* (fear of foreigners or strangers).

Therapists use numerous approaches to treat phobias. Two popular treatments are *psychoanalysis* and *behavioral therapy,* which are based on different ideas about the causes of psychological problems.

Sigmund Freud, an Austrian physician and the founder of psychoanalysis, believed that phobias and other psychological disorders are caused by unconscious desires. According to Freud, individuals *repress* (force into the unconscious mind) desires that they have been taught are bad. Freudians believe that a phobia is a symbolic expression of these repressed feelings, such as aggressive impulses or sexual drives, and of the punishment linked with the feelings in the unconscious. In psychoanalytic treatment of phobias, the therapist and patient try to uncover such repressed feelings. Psychoanalysts believe that when a patient fully understands the repressed feelings, the fear will disappear or become manageable.

Behavioral therapy holds that a phobia is a learned response and can be unlearned. Therapists using behavioral treatments often employ techniques that involve gradually exposing the phobic individual to whatever is feared. The exposure may take place in real life or in the person's imagination. For example, claustrophobic patients may imagine themselves in smaller and smaller rooms until they can visualize a tiny space without anxiety. The gradualness of the exposure is considered important in making the treatment effective and relatively painless. A popular technique called *systematic desensitization* combines gradual exposure with relaxation or other experiences to reduce anxiety.

Many therapists who treat phobias conduct group therapy in addition to individual treatment. Group therapy enables phobic patients to talk with others who have the same fears and learn from one another. Some therapists also use hypnosis to help phobic patients face their fears. E. B. Fisher, Jr.

Phoebe, *FEE bee,* is the name of several species of small birds. The name comes from the male phoebe's call, which sounds like "fee-bee." The *eastern phoebe* is common throughout eastern North America in summer.

The eastern phoebe has brownish-gray feathers.

It has a brownish-gray back and a mostly white breast. measures $6\frac{1}{2}$ to 7 inches (16 to 18 centimeters) in lengt The eastern phoebe nests on rafters and beams, in roc hollows, or under bridges. It builds a nest of weeds, grasses, and mud, and covers it with mosses. The bird usually lays three to six white eggs with pale brown spots. It eats insects that it catches in flight.

Scientific classification. Phoebes are in the tyrant flycatche family, Tyrannidae. The scientific name for the eastern phoebe *Sayornis phoebe.*

Phoenicia, *fih NIHSH uh* or *fih NEE shuh,* was the name the ancient Greeks gave to the region which is now roughly the coastal areas of Syria, Lebanon, and Is rael. The Eleutherus River formed the northern boundary and Mount Carmel the southern. This region lay be tween the Lebanon Mountains to the east and the Mediterranean Sea on the west.

The word *Phoenicia* may have developed from the word *Canaan,* meaning *land of purple,* the name first used for ancient Palestine and Syria. Canaan was a mai source of red-purple dyed goods. The Greeks probabl used their word *phoinix,* which meant *red-purple,* whe referring to the people who traded these red-purple goods to them. *Phoínike,* or *Phoenicia,* eventually became the name of Canaan's coastal strip.

The Phoenicians were one of the great peoples of th ancient world. They were great sailors, navigators, and traders. The Phoenicians were among the first to send out explorers and colonists throughout the Mediterranean Sea area, and even beyond the Strait of Gibralta The Greek alphabet developed from that of the Phoeni-

Way of life

Phoenicians cannot be easily distinguished from other ieoples who lived in Canaan before the Israelites set- ed there. For this reason, the Phoenicians are some- mes called *Canaanites* in the Old Testament. More of- en, they are called *Sidonians,* from the name of the 'hoenician city of Sidon. Scholars now know that the orthern Phoenician city of Ugarit (now Ras Shamra in vestern Syria) was in contact with Cretan civilization as arly as 1900 B.C. Between 1400 and 1200 B.C., a Myce- iaean colony thrived at Ugarit.

Language. The Phoenicians spoke a dialect of the Se- nitic languages. The Phoenician language was closely elated to Hebrew. It was more distantly related to Ara- naic and to the Semitic languages of Mesopotamia, uch as Assyrian and Babylonian. Scholars once be- ieved that the Phoenicians had invented their alphabet ndependently. But later discoveries indicated that they iad adapted it from earlier writing. The Phoenician al- ıhabet consisted of 22 consonant signs. The Greeks ıdded the vowel signs later.

By the beginning of the Christian Era, Aramaic had be- :ome the language of Phoenicia. But North Africans iear the former Phoenician colony of Carthage contin- ıed to speak the Phoenician language until the A.D. i00's, using a dialect called *Punic.* Some names of places n southern Spain, colonized by the Phoenicians in the '00's B.C. or earlier, come from the Phoenician language. The name of *Gades* (now Cádiz, Spain) comes from the Phoenician word for *wall.* The word *bible* comes from the Greek word for *book.* The Greeks took this word from the Phoenician city of Byblos, a trading center for papyrus.

A few fragments of Phoenician literature have survived in Greek translation. Since 1929, important discoveries have been made at the site of ancient Ugarit. Religious inscriptions on clay tablets found there clarify some formerly obscure passages in the Old Testament. The tablets were written in cuneiform, in an alphabetical style that differs from the standard Phoenician.

Trade and manufacturing. The Phoenicians were seagoing traders from the very beginning of their recorded history. The Egyptians knew about the "ships of Gebal" (Byblos) as early as 2900 B.C. But Phoenicia did not reach its peak as a great sea power until about 1000 B.C., and after.

The city of Sidon grew famous for its purple dye, and developed a well-known glass industry. Tyre also had a purple-dyeing industry, and became noted for the bad odor which the dye works caused. Phoenicia was one of the garden spots of the Roman Empire, and exported wine, oil, and laurel and cedar wood, as well as textiles and other manufactured goods.

The Phoenicians learned most of their methods of manufacturing from the Egyptians. They cast, hammered, and engraved metals, such as gold and silver. They carved many objects from ivory, including pieces of furniture. From early times, Phoenicians knew how to weave woolen and linen cloth. The craftworkers dyed

the cloth and often sewed it into robes before they sold it. The Greeks later adopted the *keton,* a Phoenician shirtlike garment.

Religion. Phoenicians had many gods and goddesses called *baal* (lord) and *baalat* (lady). All Phoenicians worshiped the same major gods, although these gods sometimes were known by different names in different cities. For example, Melqart, god of Tyre, could also be thought of as the *Baal* of Tyre. The Phoenicians practiced sacrifices similar to those practiced by most other Semitic peoples. But they also offered human sacrifices in Phoenicia and in their colonies, which gained for them a reputation for cruelty.

The story of Astarte and her lover Adonis, well-known in Phoenicia, was carried from there to Greece, where Astarte became the Greek goddess Aphrodite. The Romans later knew her as Venus. The tragic death of her lover by the tusks of a wild boar and her lament for him comes down to us through Greek, Latin, and English literature in the story of Venus and Adonis.

Government. The ancient Phoenicians lived in a number of independent city-states. Like the Greeks, they never united their cities into a single country. These cities originally were aristocracies ruled by kings. Beginning in the 800's B.C., councils of elders ruled with the kings, and some of the councils were more powerful than the kings. Later, most cities were ruled by government officials called *shofets.* Most of the Phoenician mountains came down to the sea, and the ancient towns were originally built on islands, like Tyre and Arvad, or occupied a small harbor area on the mainland with hills in back of it. The most important of these coastal cities were Acco, Arvad, Berytus (now Beirut), Byblos, Sidon, and Tyre. Beirut, the present-day capital and chief seaport of Lebanon, is the only city still important.

History

Foreign control. Phoenicia was a natural meeting place for foreign cultures, because it lay on the main avenue of traffic between Egypt to the south and Asia Minor and Mesopotamia to the east. Egypt exerted the earliest influence on the Phoenicians. As early as the time of the Old Kingdom, from 2686 to 2181 B.C., Egypt was importing the famed cedars of Lebanon. By the time of the Middle Kingdom, from 2052 to 1786 B.C., the two countries had established regular trade. The Phoenicians exported timber and pitch, and imported gold and manufactured articles. In the 1400's B.C., Phoenicia became a frontier province of Egypt, and remained one for about 100 years. During this period, the Phoenician cities influenced Egypt almost as much as Egypt influenced them. Phoenician nobles often visited the Egyptian court. Phoenician cults and religious ideas affected Egyptian thought.

Babylonian culture also influenced early Phoenicia. By the 1300's B.C., the princes of Phoenicia were writing in Babylonian cuneiform (see **Cuneiform**). The Phoenicians learned to seal their documents with Babylonian cylinders and seals. The Babylonians also taught the Phoenicians many of their mythological tales about the beginning of the world, the birth of the gods, and the creation of human beings. Some scholars believe that Phoenicia may have been the channel through which the Babylonian legends about the creation and the flood passed to the Hebrews farther south and to the Greeks.

For a short period in the 1200's B.C., Phoenicia came under the Hittite sphere of influence, but gained its freedom when the Hittite Empire collapsed.

The spread of Phoenician influence. The Phoenician cities gained their independence about 1100 B.C. For the next 250 years, they stood at the height of their power and prosperity. There were Phoenician settlements on the island of Cyprus even before the 1100's B.C. After that date, Phoenician sailors opened up the entire Mediterranean to their ships and commerce. They established colonies along the southern coast of Spain,

tl northern coast of Africa, and the western coast of Sily. It may be said that the western Mediterranean vs a "Phoenician lake" before the coming of the Greeks. Penicians influenced Western culture through their cony of Carthage. This greatest of all Phoenician conies in the West was founded by people from the c of Tyre about 750 B.C. Queen Dido was one of the lendary founders of Carthage (see **Dido**). Phoenician conies, including Carthage, resembled the cities of Fenicia. Many manufacturers, industrial workers, merchants, and sailors lived there.

The city of Tyre seems to have played the main part i the colonizing activity of the Phoenicians. A vivid desiption of Tyre's far-flung commerce appears in the d Testament (Ezekiel 27:3-25). When King David of Is-rl established his royal residence at Jerusalem, he uilt his palace with stone and cedars from Lebanon Samuel 5:11). The first book of Kings tells that Hiram, ig of Tyre in the 900's B.C., was a friend of David's sucssor, King Solomon. When Solomon built his famous mple, he asked Hiram for firs and cedars from banon. When Solomon built a navy, Hiram lent him ipmen that had knowledge of the sea" (I Kings 9:27). e base of this fleet was the Red Sea port of Ezion-ber on the Gulf of Aqaba. This site contains the reins of a once great smelting and mining center. Hin and Solomon combined to send from this port eat fleets of merchant vessels, which came back ded with "gold and silver, ivory and apes and peacks" (II Chronicles 9:21). In return, Solomon traded ain, olive oil, wine, and other agricultural products th Hiram.

Some scholars believe that Phoenician influence and rhaps Phoenician colonists reached Corinth and ebes on the mainland of Greece. This tradition of oenician colonization in Greece may be exaggerated. t the Phoenicians appear in the poems of Homer as lled artisans, merchants, and sailors. The Phoenician habet also reached Greece soon after 800 B.C.

Control of both sides of the Strait of Gibraltar gave the oenicians access to the Atlantic Ocean. They establhed a trading monopoly along the coasts of northstern Africa and western Europe. Some scholars beve that the Phoenicians may have sailed as far as rnwall, in southwestern Britain, and worked the tin nes there. Phoenicians sailed around Africa in the 0's B.C., some 2,000 years before the Portuguese did in D. 1497. The Greek historian Herodotus tells this story the fourth book of his *History*.

Decline. The Assyrians captured the Phoenician cities 842 B.C. For the next 200 years, Phoenicia was conlled by Assyria. This period was one of hardship, relt, and suppression. After the downfall of the Assyris in 612 B.C., Phoenicia was briefly controlled by the bylonians. Later, it became part of the Persian Empire eated by King Cyrus I (see **Cyrus the Great**). At this ne, the city of Sidon seems to have surpassed Tyre in portance. Under Persian rule, Phoenician cities prosred and the Phoenicians were still considered excelnt shipbuilders and sailors. During the Persian Wars, 0-479 B.C.), the Phoenician fleet was the strongest arm the Persian Navy in its attack upon Greece. Herodotus ys that in this fleet the king of Sidon ranked second to rxes, the Persian ruler (see **Xerxes I**). But the Phoenician fleet was almost completely destroyed by the Greeks at the Battle of Salamis in 480 B.C.

Phoenicia came under Greco-Macedonian rule when Alexander the Great captured the city of Tyre in 332 B.C. His successors, the rulers of Egypt and Syria, fought among themselves for possession of the Phoenician cities and for control of their shipbuilding and commercial resources. During this period, the culture of Phoenicia changed. Greek gradually became the language of literature and learning. Aramaic, which had earlier replaced the Phoenician language, became the language of the marketplace and of the common people. Many philosophers of the time, including Zeno of Sidon and Diodorus of Tyre, were of Phoenician origin.

In 64 B.C., the Roman general Pompey the Great made Phoenicia part of the Roman province of Syria. The Romans established a famous law school at Beirut. Tyre and Sidon became centers of learning and prospered commercially. Tyre became known for the manufacture of fine glass. Phoenicia and the rest of Syria fell to Muslim invaders in the A.D. 600's. Phoenix, *FEE nihks,* is the capital and largest city of Arizona. It is also a manufacturing center and a major winter-resort area. Phoenix lies in the Salt River Valley, a flat region ringed by low mountains.

The city has a warm, sunny, dry climate. Winter temperatures may reach 70 °F (21 °C) or higher. The city's climate attracts many visitors. The sun shines about 300 days a year. Early resorts in Arizona once offered visitors free rooms and meals on days the sun did not shine.

White pioneers first settled in the Phoenix area in the 1860's. Two of them, Jack Swilling and Darrel Duppa, noted that an ancient civilization, that of the Hohokam Indians, had once thrived in the valley. Duppa predicted that a great city would rise on the site. He named their settlement *Phoenix* for the mythical bird that rose from its own ashes every 500 years. In the mid-1900's, Phoenix became one of the fastest-growing cities in the United States. In 1950, it ranked 99th in population among the nation's cities. By 1980, it had jumped to 9th. By 2000, Phoenix had become the 6th largest city in the United States. The climate—and the widespread use of air conditioning—helped bring about the rapid growth.

The city

Phoenix and its neighboring communities lie in the broad, flat Salt River Valley, which is surrounded by mountains. The Salt River flows westward through Phoenix and becomes part of the Gila River a few miles southwest of the city. The Salt and Gila are usually dry in the Phoenix area. They have been dammed east of the city to collect water for irrigation.

The Salt River Valley was originally desert, and water has always been a critical need in the Phoenix area.

Phoenix, the capital and largest city of Arizona, lies in a desert valley ringed by mountains. The city experienced enormous growth in the mid-1900's, partly because of its warm, sunny climate. Office buildings rise in the downtown area, *shown here.*

Since 1986, Phoenix has received water from the Colorado River on Arizona's western border through aqueducts of the Central Arizona Project.

Layout of Phoenix. The city of Phoenix covers 450 square miles (1,165 square kilometers) and is the seat of Maricopa County. Phoenix began as a trading center for a farming district that covered much of the Salt River Valley. Urban growth has eaten up much of the farmland, but the distance between downtown office buildings and farms where cotton, grains, and vegetables grow is still only a few miles.

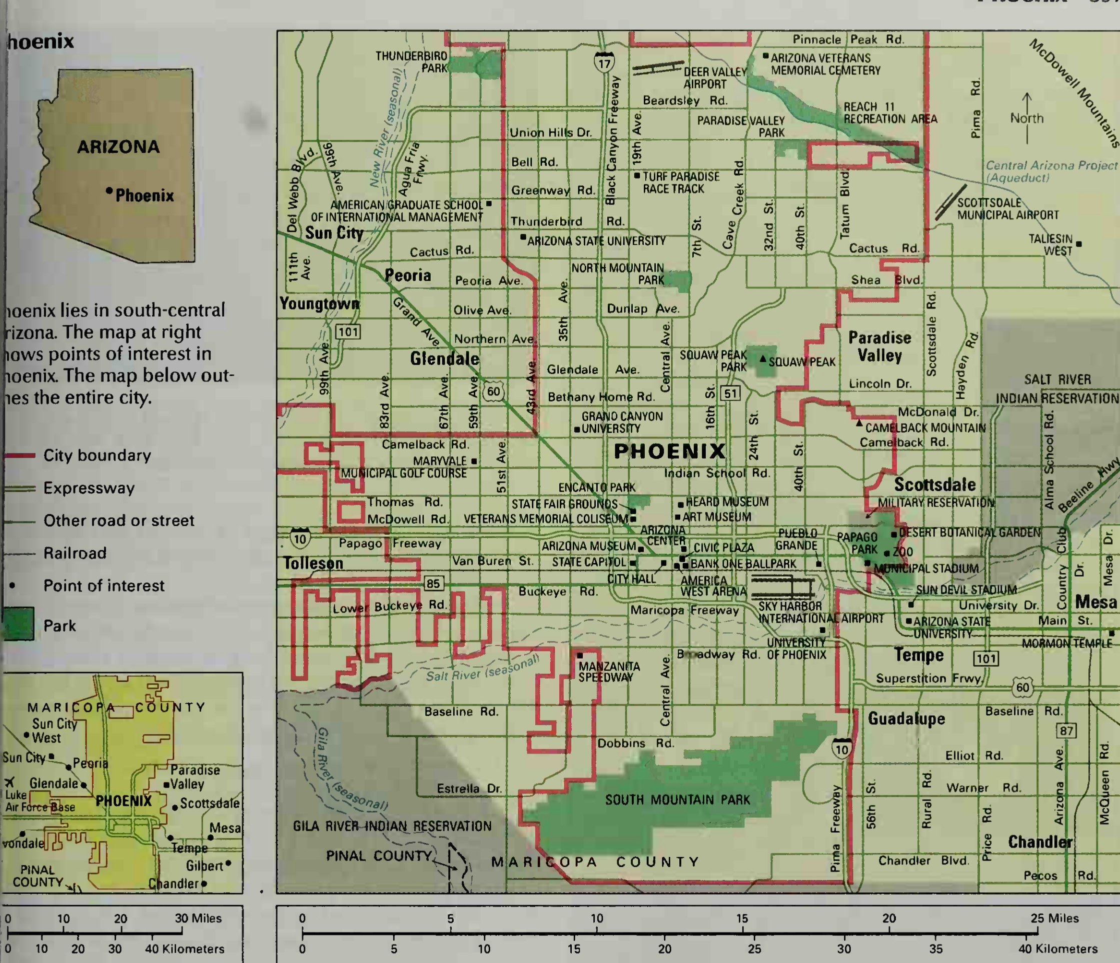
Downtown Phoenix is near the center of the city. There, high-rise buildings extend along Central Avenue, forming the city's financial district. Downtown also includes City Hall, the Arizona State Capitol, and other government buildings. Also in the area are the Phoenix Civic Plaza, which includes a symphony hall and several large exhibition areas; America West Arena; and Arizona Center, a complex of offices and shops.

Residential areas, with their shopping malls, spread out beyond the downtown area. A few *buttes* (steep hills) pop up in the middle of the urban area. For example, Camelback Mountain rises 2,704 feet (824 meters) in an expensive residential area in eastern Phoenix. Squaw Peak, which rises 2,608 feet (795 meters) in the northern part of the city, is popular for hiking.

The metropolitan area is sprawling and spacious. The residential areas of the city blend into adjoining cities and towns. These communities include Glendale, Paradise Valley, Scottsdale, and Tempe. Mesa lies east of Tempe. It is the area's second largest city.

The Phoenix urban area includes all of Maricopa County. The United States Census Bureau classifies Maricopa County and Pinal County as the Phoenix-Mesa metropolitan area, which covers about 14,600 square miles (37,800 square kilometers). Nearly two-thirds of the people of Arizona live in the fast-growing area, which increased in population by more than 1 million betwee 1990 and 2000.

People



The people of Phoenix are called Phoenicians. The city's climate has drawn many residents from other par of the United States. Only about one-third of the peopl were born in the Phoenix area.

Ethnic groups. Non-Hispanic whites account for about 56 percent of the city's population. Hispanics make up about 34 percent of the population, and African Americans about 5 percent. American Indians and Asians each make up less than 2 percent.

Housing. Phoenix is largely a city of single-family homes. Following World War II (1939-1945), newcomer began flocking to Phoenix. Phoenix contractors bought up farmland and built sprawling subdivisions of single-family homes. In some areas, such as the Maryvale district of west Phoenix, they constructed houses that wer modest and affordable. More expensive housing tende to be concentrated in northeast Phoenix and in adjoining Scottsdale. The largest Hispanic and African-American neighborhoods are in southern Phoenix.

Since the 1960's, retirement communities have addec a new element to the population and housing patterns of the Phoenix area. Such large developments were bui especially for retirees. The largest ones include those a Sun City and Sun City West, northwest of Phoenix, and in the Mesa and Chandler regions in the southeast.

Education. Maricopa County has about 500 public e ementary and high schools, with a total of more than 440,000 students. About 130 parochial schools, with a to tal of more than 19,000 students, also operate in the county. The county has one of the largest systems of two-year community colleges in the nation. Most of Ari

ona's four-year universities and colleges are in the hoenix area. The largest one, Arizona State University, as its main campus in Tempe and a smaller campus in vestern Phoenix. The Frank Lloyd Wright School of Ar-hitecture is located in Scottsdale at Taliesin West.

Social problems. Violent crime is a problem in hoenix, as in other large urban areas. Much of the rime is associated with gang activity and drug abuse.

Phoenix also is plagued by air pollution, much of vhich results from automobile exhaust. The only form of nass transportation is a bus system that draws relatively ew riders. Most residents drive cars.

Cultural life

The arts. Phoenix is the home of the Phoenix Sym-ıhony Orchestra, the Arizona Theater Company, and ıallet Arizona. The area's major theaters include the Her-ıerger Theatre Center in downtown Phoenix, Symphony ıall in Phoenix Civic Plaza, the Sundome in Sun City, and Grady Gammage Auditorium at Arizona State University n Tempe. The auditorium, completed in 1964, was the ast major public building designed by architect Frank loyd Wright.

Museums and libraries. The Heard Museum of An-hropology and Primitive Art in Phoenix concentrates on American Indian culture. The collection of the Phoenix Art Museum includes European and Asian art and contemporary art of the U.S. Southwest. The Phoenix Museum of History chronicles the settlement and growth of Phoenix. The nearby Scottsdale Center for the Arts exhibits contemporary and historical art.

The Phoenix Public Library has 11 branches. Maricopa County maintains 11 libraries throughout the county.

Recreation. Many Phoenix residents enjoy outdoor life, which the mild climate favors. Popular activities include trips to nearby mountains and boating on lakes built to store irrigation water. The metropolitan area has about 100 golf courses.

The Phoenix Zoo is located in Papago Park, an area of stone buttes on the border between Phoenix and Tempe. The Desert Botanical Garden, also in the park, features plants native to deserts throughout the world. Phoenix South Mountain Park, in southern Phoenix, is the largest municipal park in the United States. It covers over 16,500 acres (6,677 hectares).

The Phoenix Suns of the National Basketball Association and the Phoenix Coyotes of the National Hockey League play in the America West Arena. The Arizona Diamondbacks of the National League play baseball in Bank One Ballpark. The Arizona Cardinals of the National Football League play in Sun Devil Stadium in Tempe. tomobile races. Turf Paradise Race Track, in northern Phoenix, hosts a winter season of horse races.

Major annual events recall the area's Western heritage. They include the Phoenix Jaycees Rodeo of Rodeos and the Arizona National Livestock Show.

Economy

Service industries, particularly tourism and government activities, play a key role in the economy of the Phoenix area. Manufacturing also contributes heavily to the economy.

Service industries. Tourists flock to the Phoenix area. Many vacation resorts, golf courses, and other tourist-related facilities operate there. Tourism generates much income and employment. It is a year-round industry. But the tourist facilities are busiest during winter, when visitors come to escape cold weather back home.

Other service industries include government and military activities. State, county, and city governments operate in Phoenix and provide many jobs. Luke Air Force Base, at Glendale, also contributes to the economy.

Manufacturing. The Phoenix area's chief manufactured products include aircraft, aircraft engines and parts, computers, guidance and navigation equipment,

and semiconductors. The area's products also include agricultural chemicals, air-conditioning equipment, and cosmetics.

Transportation and communication. Phoenix Sky Harbor International Airport ranks among the nation's busiest airports. It is home base of America West Airlines. Passenger and freight railroad lines and more than 150 trucking companies serve the city. Phoenix has one daily newspaper, *The Arizona Republic*.

Government

Phoenix has a council-manager form of government. The voters elect a mayor and eight city council members. The mayor serves a four-year term. The council members are elected initially to a two-year term, and they may be reelected to four-year terms. The council hires a city manager to carry out its policies, to prepare the city budget, and to appoint and dismiss department heads.

History

Settlement. Hohokam Indians lived in the Salt River Valley from about 300 B.C. until the 1400's. They constructed a system of canals to take water from the Salt

d Gila rivers to irrigate their crops. In 1539, Spanish plorers became the first whites to reach the area. The ea belonged to Spain from 1539 until 1821, when it as taken over by Mexico. The area became part of the ited States in 1848, when the U.S. defeated Mexico in e Mexican War.

The Phoenix area was part of the New Mexico Territo- from 1850 until 1863, when the U.S. government creat- the separate Territory of Arizona. Prescott, in the rthern part of the territory, became the capital.

In 1865, the United States established a military post med Camp McDowell northeast of the future site of oenix to protect the road between Tucson and escott. Farmer John Y. T. Smith settled in the area and ew hay to sell to the Army at Camp McDowell. Mari- pa and Pima Indians lived in the area at that time.

In 1867, adventurer Jack Swilling led a party of men to e Salt River Valley to build new irrigation canals. In me places, the men simply dug out the old Hohokam nals. Swilling's group included Englishman Darrel uppa, who gave the settlement the name *Phoenix.* owever, Swilling's settlement was about 4 miles (6.4 ometers) east of what became the official site of oenix. In 1870, settlers selected and surveyed the offi- al town site, in what is now the downtown area, mark- g the founding of Phoenix. Phoenix was incorporated a city in 1881.

Early developments. Because of the mild winters d year-round growing seasons, Phoenix prospered d other towns were established nearby. Branch rail- ads connected Phoenix to the Southern Pacific (now nion Pacific) Railroad's main line in 1887 and to the nta Fe's main line (now part of Burlington Northern nta Fe Corporation) in 1895. The city became a center r trading and processing farm products.

The Salt River caused problems. At times, it was near- dry; but at other times it flooded and carried away rms and houses in low-lying parts of the city. In the rly 1900's, builders constructed Theodore Roosevelt am 55 miles (86 kilometers) northeast of Phoenix to ntrol the Salt's flooding and to store water until it was eded to irrigate crops. The dam began operations in 11. It assured the city a steady supply of water. Devel- pers began to attract more settlers to the area.

Phoenix was named the capital of the Territory of Ari- na in 1889. Arizona became a state in 1912, and oenix remained the capital. By 1920, Phoenix, with a pulation of 29,053, had become Arizona's largest city.

The Phoenix area's first resort for winter visitors, the gleside Inn, opened in 1910. The winter tourist trade gan to flourish.

Dramatic growth. The growth of Phoenix was steady ut modest until the beginning of the 1940's. In 1940, the pulation had reached 65,414. Phoenix then entered a riod of tremendous growth.

During World War II, the armed forces used the oenix area for training in aviation and desert warfare. fter the war ended in 1945, many former members of e military who had trained in Arizona returned to the oenix area to live and to raise families.

Beginning in the 1950's, air conditioning became com- on in the United States. Summer temperatures in oenix often reach 100 °F (38 °C) or higher. Air condi- oning made living in the desert climate of Phoenix more comfortable. Large numbers of retired people be- gan to move to the area. The establishment of new in- dustries in Phoenix also contributed to the city's growth. This development was part of a national trend of indus- trial growth in the so-called *Sun Belt,* or areas with warm climates.

Phoenix steadily annexed surrounding areas to allow for continued growth. In 1950, the city covered only 17 square miles (44 square kilometers). Its size has since in- creased to 450 square miles (1,165 square kilometers). The annexations also resulted in population growth. To accommodate the population, thousands of single-fami- ly dwellings were built on former farmland and even in parts of the desert.

The population of Phoenix reached 106,818 by 1950. Then, in just 10 years, the population quadrupled—soar- ing to 439,170 in 1960. In 1950, Phoenix had ranked as the 99th largest U.S. city in population. By 1980, with 789,704 people, the city ranked 9th.

Recent developments. Through the years, outside sources of water have been necessary for the continued growth of Phoenix. In 1968, the United States Congress authorized funds to build the Central Arizona Project. This project was designed to bring water from the Col- orado River along Arizona's western border to Phoenix and other parts of the state. Phoenix began receiving wa- ter from the project in 1986.

During the 1950's and 1960's, downtown Phoenix lost many of its businesses when companies moved to new suburban shopping malls. However, since the 1970's, the city has redeveloped much of its downtown area. Builders completed a new city hall in 1993 and a new central library in 1995.

The Phoenix area has continued to grow. By 2000, the city's population had reached 1,321,045. Outlying com- munities also grew, and Phoenix is now the hub of a metropolitan area of more than 3 $\frac{1}{4}$ million people.

Phoenix, *FEE nihks,* was a fabled bird in Greek mythol- ogy. Only one such bird existed at any time, and it was always male. It had brilliant gold and reddish-purple feathers, and was as large or larger than an eagle. Ac- cording to some Greek writers, the phoenix lived exactly 500 years. Other writers believed its life cycle was as long as 12,954 years.

At the end of each life cycle, the phoenix burned itself on a funeral pyre. Another phoenix then rose from the ashes with renewed youth and beauty. The young phoenix, after rising from the ashes, carried the remains of its father to the altar of the sun god in the Egyptian city of *Heliopolis* (City of the Sun). The long life of the phoenix, and its dramatic rebirth from its own ashes, made it a symbol of immortality and spiritual rebirth.

The Greeks probably took their idea of the phoenix from the Egyptians, who worshiped the *bennu,* a sacred bird similar to the stork. The bennu, like the phoenix, was connected with the sun worship rites in Heliopolis. Both birds represented the sun, which dies in its flames each evening and emerges each morning.

Phonetics, *foh NEHT ihks* or *fuh NEHT ihks,* is the sci- ence of speech sounds and the symbols by which they are shown in writing and printing. This science is based

on a study of all the parts of the body concerned in making and hearing speech. It includes the positions of the parts of the body necessary for producing spoken words, and the effect of air from the lungs as it passes through the larynx, pharynx, vocal cords, nasal passages, and mouth. Phonetics also deals with the physical properties of sound—such as *frequency* and *amplitude*—that permit people to hear speech sounds as different from one another. For a discussion of these properties, see **Sound** (The nature of sound).

An international phonetic alphabet is used to represent speech sounds symbolically. The symbols can be applied to all languages. In English, they show the difference between the *th* of *ether* (θ) and the *th* of *either* (ð), and between the *ssi* of *mission* (ʃ) and the *si* of *vision* (ʒ). Another symbol shows the *ng* sound of *sing* (ŋ). Phonetic symbols are especially useful for vowel sounds, as in the *a* of *father* (ɑ) and the *a* of one pronunciation of *ask* (a),or the *u* sound of *pull* (ʊ), the *oo* sound of *pool* (u), and the stressed *u* sound of *sun* (ʌ). The most common sound in the English language is that of *e* in ag*e*nt. It appears in print as *a*round, mom*e*nt, char*i*ty, porp*oi*se, act*o*r, and circ*u*s. Its symbol is an inverted *e* (ə), *called a schwa.*

Phonetics and spelling. The *phonetic ideal* is the term for a language in which every spoken sound is represented by one letter and only one. No language has reached this ideal. German and Spanish add a few marks to letters, because those languages have too few letters to cover all their sounds. Italian has only one silent letter, *h*, which is used before *e* and *i* to make the preceding *g* or *c* hard, as in *spaghetti.* French is among the most complex in this respect. It has many spellings for the same sound; four accent marks; and a cedilla for words like *François* that have an *s* sound for *c.*

English spelling was decided on by printers hundreds of years ago, but speech has continued to change. For this reason, English is far from the phonetic ideal. "*Though* he pulled *through* a *cough* and *hiccough,* he still had a *rough* night on a *bough,*" contains six different sounds spelled the same. Every vowel has several sounds, as in c*a*ke, h*a*t, and *a*rm. *A* and *e* have about eight sounds. English-speaking people have tried in some ways to reproduce sounds phonetically. For example, *pin* and *pine,* and *pinning* and *pining,* mark the difference in the *i* sounds. But there is no reason for a spelling difference in *till* and *until.*

Many people have sought to establish a *reformed spelling,* to bring spelling closer to sound. However, such a reform would be of doubtful value because pronunciation changes so rapidly. Marianne Cooley

Phonics, *FAHN ihks,* is the association of letters or combinations of letters with their appropriate speech sounds. Phonics also includes understanding the principles that govern the use of letters in words. In reading, phonics helps us understand the sound of a word that is unfamiliar. In spelling, phonics helps us write the appropriate letters for the sounds we hear.

Phonics can be taught synthetically or analytically. In the *synthetic* approach, a child learns the sounds of individual letters and letter combinations, usually before learning to read. With an unfamiliar word, the child *synthesizes,* or sounds out, the sounds that make up the word. In the *analytic* approach, a child develops a vocabulary of words he or she knows by sight. This is done while learning to read. The child eventually analyzes the words for their sounds. In this way, the child understands both the sound of the letters and the reasons some letters are used instead of others. The child then applies these reasons, or *principles,* and learns to recognize the sounds of new words.

In reading, phonics has both advantages and limitations. A knowledge of phonics makes it possible to reconstruct the sounds of many words not known by sight. This is particularly true for languages in which each letter or symbol represents only one sound and each sound is represented by only one letter. In the English language, the relation between sounds is not consistent. Thus, phonics has limitations if it is the only means used to learn unfamiliar words. Different letters may represent the same sound, as in *meet* and *meat,* or the same letter may stand for different sounds, as the *a* in *fall* and *fate.*

Educators consider phonics an essential part of any effective reading program. But because of the many inconsistencies in the English language, they recommend using additional aids to help a reader improve his or her pronunciation of unfamiliar words. For example, the reader may be taught to identify new words by their prefixes, suffixes, roots, and syllables. Marianne Cooley

Phonograph is a device that reproduces sounds that have been recorded on audio records. Phonographs are also called *record players.* Until the mid-1980's, they were the most common device for listening to music and other sound recordings. Today, most people have replaced their record collections with cassette tapes and compact discs. Compact disc players produce better sound than phonographs do. Compact discs also are more durable than records. However, many people still use phonographs to listen to older recordings.

How phonographs work. Phonographs play records that have been produced by a process called *analog disc recording.* In this process, an *analog* (likeness) of the original sound waves is stored as jagged waves in a spiral groove on the surface of a plastic disc. As the disc rotates on the phonograph, a needle, called a *stylus,* rides along the groove. The waves in the groove cause the stylus to vibrate. These vibrations then are transformed into electric signals and converted back into sound by speakers.

Most phonograph records are thin plastic discs with a diameter of 7 or 12 inches (18 or 30 centimeters). A 7-inch record is played at a speed of 45 revolutions per minute (rpm) and has only a few minutes of sound per side. A 12-inch *long-playing* (LP) record is played at $33\frac{1}{3}$ rpm and holds about 30 minutes of sound per side. A 12-inch single holds several minutes of sound per side and is also generally played at $33\frac{1}{3}$.

Parts of a phonograph. There are six main parts of a phonograph. These parts are: (1) the turntable, (2) the drive system, (3) the stylus, (4) the cartridge, (5) the tone arm, and (6) the amplifier.

The turntable is a flat metal plate covered with rubber on which the record sits. Most turntables operate at 33 and 45 rpm. Some turntables also operate at 78 rpm, a playback speed used in making records until the 1950's.

The drive system spins the turntable. Most phono-raphs are equipped with a *direct drive.*

In a direct drive system, the turntable is mounted di-ectly on the motor shaft. The speed of the motor, which an be varied, determines the speed of the turntable's otation.

The stylus is a piece of diamond or extremely hard ynthetic material shaped somewhat like a cone. The sty-us is suspended from one end of a flexible strip of met-. The other end of the metal strip is attached to the car-idge.

The stylus vibrates as it rides in the groove of a ecord. In a stereophonic phonograph, the stylus re-ponds to two separate sets of waves—one on either de of the groove. These two sets of waves correspond the two stereo sound channels.

The cartridge receives vibrations from the stylus and ansforms them into electric energy. Most cartridges enerate voltages when the motion of the stylus moves n electric coil in a magnetic field or moves a magnet ear a coil. A stereophonic cartridge changes the stylus ibrations into two sets of electric signals—one for the ght sound channel and one for the left.

The tone arm, also called the pickup arm, holds the artridge and stylus. In most record players, the tone rm is mounted on a pivot. The pivot lets the stylus ride e record groove in an arc across the disc. The pres-ure of the stylus is controlled by a weight at the pivot nd of the tone arm. Too much pressure causes poor ound quality and increased record wear. If there is too ttle pressure, the stylus will skip across the record. Vires along the tone arm carry electric signals from the artridge to the amplifier.

The amplifier boosts the power of the weak signals om the cartridge so that they reach the speakers in suf-cient strength. The speakers convert the electric sig-als to sound waves (see **Speaker**).

How phonograph records are made. The produc-on of most records begins with making a *master* (origi-al) tape recording in a studio or concert hall. Such ecordings are made using tape recorders capable of ecording many separate *tracks* (channels of sound). In roducing the master tape, an engineer records differ-nt instruments or groups of instruments on separate acks. During recording, various aspects of sound qual-y can be controlled separately for each track. In addi-on, each track can be recorded and played back alone or in combination with other tracks. See **Recording industry** (In a recording studio).

Often, the engineer records several *takes* (separate recordings) of a section of music. After recording, the editing engineer selects the best take of each section of music. The engineer edits the music electronically to create a new master tape. The new tape has the sections from different takes arranged as though they had been recorded in a single performance. The engineer uses a process called *mixdown* to reduce the number of tracks to the two needed for a stereophonic record.

The next step in making a phonograph record is the creation of a master lacquer. A lacquer is an aluminum disc coated with nitrocellulose lacquer. A blank lacquer is rotated on the turntable of a machine called a *record-cutting lathe.* Electric signals from the master tape are fed to a *cutting head* on the lathe. A *cutting stylus* on the cutting head cuts a wavy, V-shaped groove that spirals toward the center of the disc. This stylus is connected to two electric coils. Each electric coil is near a separate electromagnet.

In making a stereo lacquer, electric signals corresponding to the right channel magnetize one coil. Those corresponding to the left channel magnetize the other coil. The magnetic changes in the coils cause the stylus to move up and down and from side to side. The stylus thus cuts waves for the left channel on one side of the groove, and it cuts waves for the right channel on the other.

Next, a *metal master* is made from the master lacquer by a process called electroplating (see **Electroplating**). In this process, the surface of the master lacquer is coated with nickel. When separated from the lacquer, this nickel plate forms a metal master—a negative copy that has ridges where the lacquer has grooves. Plating the metal master produces a *mother*—a positive copy of the lacquer. The mother itself is then plated several times to create multiple negative copies called *stampers.*

Two stampers, one for each side of the disc, are mounted in a hydraulic press. A piece of plastic called a *biscuit* is placed between the stampers and squeezed in the press. Steam circulating through the press softens the plastic, which is imprinted with record grooves from both stampers. After the record is imprinted, cool water stiffens the disc.

History. The first practical phonograph was invented in 1877 by the U.S. inventor Thomas A. Edison. Edison's

device could record sound on tinfoil wrapped around a small metal cylinder, and then replay the sound. The cylinder rotated on an axle that was turned with a hand crank. A needle attached to a *diaphragm* (vibrating disc) was placed against the cylinder. As someone spoke into a mouthpiece, the sound waves made the diaphragm and needle vibrate. These vibrations caused the needle to make dents in the foil on the rotating cylinder. To play back the sound, another needle attached to a diaphragm was placed against the cylinder. As the cylinder was rotated, the dents in the foil made the needle and diaphragm vibrate. These vibrations created sounds roughly like the original sound. This type of recording is called *acoustic recording* because the sound is produced without electrical energy.

In 1885, the U.S. scientists Chichester Bell and Charles S. Tainter improved upon Edison's invention by recording on cardboard cylinders coated with wax. This new recording material produced better sound.

In 1887, Emile Berliner, a German immigrant to the United States, invented the Gramophone—a phonograph that used shellac discs. These discs provided better sound, were more durable, and could be mass-produced more easily than could cylinders.

The first electrically recorded phonograph records appeared in 1925. In addition, manufacturers began producing phonographs with electric motors and amplifiers, which greatly improved the quality of recorded sound.

Until 1948, most commercial disc recordings were made of a mixture of clay and shellac and were played at 78 rpm. In that year, the plastic 33 $\frac{1}{3}$-rpm LP record appeared on the market. It had been developed at the Columbia Broadcasting System Laboratories under the direction of Peter Goldmark, a U.S. electrical engineer. The LP held much more recorded sound and was more durable than the 78-rpm disc. In 1949, the 45-rpm disc was introduced by Radio Corporation of America (now RCA Corporation) to compete with the LP.

Growing interest in high fidelity in recorded sound led to the appearance of stereophonic phonographs and discs in 1958. Previously, records and phonographs were *monaural,* or monophonic. Such records and record players reproduce sounds from only one channel. By the late 1960's, almost all new phonographs and records were stereophonic.

Audio compact discs were introduced in Japan and Europe in 1982, and in the United States in 1983. Their superior sound quality and durability quickly made them popular. Today, few new recordings are issued on phonograph records. Ken C. Pohlmann

Phosphate, *FAHS fayt,* is any chemical compound that contains the phosphate group. The phosphate group consists of one phosphorus atom and four oxygen atoms. Its chemical formula is PO_4^{3-}.

In living organisms, cells use compounds containing phosphates to store and release energy. Phosphates are also part of DNA (deoxyribonucleic acid) and RNA (ribonucleic acid), the substances that determine a cell's form and function. In addition, the phosphate mineral hydroxyapatite is an important part of bones and teeth.

There are large amounts of natural phosphates. They occur in phosphate rocks and in the remains of organisms. The main commercial sources of phosphate rock include deposits in China, Morocco, Russia, and the United States. Processors use most phosphate rock to produce fertilizers. They crush the rock to make dry fertilizers. They make superphosphate, a liquid fertilizer that acts much faster than the pulverized rock, by treating the crushed rock with sulfuric acid.

At one time, phosphates were widely used in the manufacture of detergents. The phosphates help remove dirt and soften hard water. Unfortunately, detergents in waste water carry phosphates into lakes and streams, where the compounds cause algae to multiply. As the algae die, the process of their decay uses up oxygen needed by fish and other aquatic life. This problem led some U.S. cities and states to ban phosphate detergents. Emily Jane Rose

Phosphorescence, *FAHS fuh REHS uhns,* is the light certain substances give off when they absorb energy. The general term for the emission of light due to the absorption of energy is *luminescence.* The term *phospho-*

scence refers to luminescence that continues after the
ergy source has been removed. It may last for sec-
ds, hours, or even days. Luminescence that occurs
ly while a substance is exposed to energy is called *flu-
escence.* See **Fluorescence; Luminescence.**
The energy to create phosphorescence may be sup-
ed by various sources, including electric current, ul-
violet rays, X rays, and certain chemical reactions. The
lor of the phosphorescent light depends on the sub-
nce and the form of energy it absorbs.
Familiar phosphorescent substances include cellu-
d, eggshells, ivory, and paraffin. Many gems, miner-
, and pigments phosphoresce strongly when excited
nuclear or ultraviolet radiations. Some materials
osphoresce simply by being exposed to sunlight.
anufacturers may use such materials in toys or the
rkings on watch faces that glow in the dark. The
osphorescence given off by living things is called *bio-
minescence* (see **Bioluminescence**).
For a substance to phosphoresce, the electrons in its
ms must absorb energy. This energy causes the elec-
ns to become *excited*—that is, to jump to a higher en-
gy level. Excited electrons are unstable. To drop back
their normal energy level, the electrons give off the
cess energy as light. But in a phosphorescent sub-
nce, the electrons become trapped temporarily be-
een the excited energy level and the normal level.
Phosphorescence serves as a valuable tool in the sci-
tific examination of various materials. For example,
ysicians can diagnose certain diseases by studying
phosphorescent light given off by human tissue ex-
sed to ultraviolet rays. Archaeologists can learn the
e of pottery by heating the pottery and measuring the
ount of phosphorescence that results.
Phosphorescent substances are used to create the im-
es on computer and television screens. Tiny dots of
osphorescent material called *phosphors* coat the
eens. They phosphoresce briefly when a beam of
ctrons strikes them. We see a continuous picture as
the beam sweeps back and forth across the screen.

Phosphoric acid, *fahs FAWR ihk,* is the most common acid of phosphorus. Manufacturers use it to make inorganic phosphate compounds, fertilizers, soft drinks, and flavoring syrups. Its normal sodium salt, Na_3PO_4, is an excellent water softener. Metal surfaces treated with phosphoric acid are highly resistant to corrosion.

Most phosphoric acid is made by one of two processes. In the wet process, naturally occurring phosphate minerals are treated with sulfuric acid. In the thermal process, pure phosphorus is burned to make phosphorus pentoxide, P_2O_5, which produces the acid when dissolved in water. Pure phosphoric acid forms colorless crystals that melt at about 42.4 °C. It is very soluble in water. Phosphoric acid is called *orthophosphoric acid.* Its chemical formula is H_3PO_4.

Marianna A. Busch

Phosphorus, *FAHS fuhr uhs,* is a nonmetallic chemical element. It is found in every living cell and has many industrial uses. In nature, phosphorus occurs only in compounds called *phosphates.*

Plants and animals need phosphorus to live, as well as for normal growth. Plants absorb phosphorus from soil and use it in photosynthesis. People and animals take in phosphorus by eating plants and such foods as meat, milk, and eggs. About four-fifths of the phosphorus in the human body occurs in the bones and teeth. Phosphorus makes up an important part of *adenosine triphosphate* (ATP), a compound that stores energy in body tissues.

A chief source of phosphorus for industrial use is *phosphate rock,* also called *phosphorite.* The countries that mine much phosphate rock include China, Morocco, and the United States. Manufacturers make two forms of phosphorus from phosphate rock. These forms are *white phosphorus* and *red phosphorus.* They are called *allotropes* of phosphorus (see **Allotropy**).

White phosphorus is a soft, waxy solid. To prepare it, manufacturers first produce phosphorus vapor by heating phosphate rock in the presence of coke and sand. The vapor is then condensed into white phosphorus. White phosphorus combines readily with other elements. It also spontaneously ignites in air at about room temperature. For this reason, white phosphorus is usually stored underwater. White phosphorus is very poisonous and, when touched, can cause serious burns. It is also *phosphorescent*—that is, in the dark, it glows when exposed to air. Manufacturers use white phosphorus in making such products as steel, plastics, insecticides, fertilizers, drugs, animal feed, water softeners, and detergents. Detergents made with white phosphorus are rich in phosphates. But phosphates from the detergents can enter lakes and rivers through sewage and contribute to the *eutrophication* of the lakes and rivers. Eutrophication results in the death of fish and other aquatic life (*see* **Eutrophication**).

Red phosphorus, a brownish-red powder, is made by heating white phosphorus or by exposing it to sunlight. Red phosphorus does not burn, or combine with other elements, as readily as white phosphorus. Red phosphorus is used in the production of safety matches and pesticides.

Another allotrope of phosphorus, called *black phosphorus,* resembles graphite. It can be made by heating

white phosphorus under very high pressure. Black phosphorus combines less readily with other elements than do white and red phosphorus.

Phosphorus has the chemical symbol P. Its atomic number is 15, and its weight is 30.973762. White phosphorus melts at 44.1 °C and boils at 280 °C. The German alchemist Hennig Brand discovered phosphorus in 1669.

Phosphorus cycle, *FAHS fuhr uhs,* is the circulation of phosphorus among the rocks, soil, water, and plants and animals of the earth. Human beings and all other organisms must have phosphorus to live. In nature, most phosphorus occurs in *phosphate rock,* which contains phosphate ions (PO_4^{3-}) combined with calcium, magnesium, chlorine, and fluorine. Phosphate rock forms as sediments at the bottom of the oceans. Some of these sediments are eventually returned to land by movements of the earth's crust.

The weathering of phosphate rock that has been elevated above sea level supplies phosphates to the soil. Plants absorb dissolved phosphate from the soil. Human beings and other animals obtain phosphorus from the plants or animals that they eat. After plants and animals die, certain bacteria break down the dead organic matter and return phosphorus to the soil. Organisms may recycle phosphorus many times before it is finally washed to the sea and is trapped once again in marine sediments.

Human beings accelerate the weathering process by clearing forests and many cultivated areas that protect land from erosion. People also accelerate the phosphorus cycle by mining phosphate rock for the manufacture of such products as detergents and fertilizers. The use of these products greatly increases the rate at which phosphorus returns to the sea. Large quantities of phosphate that come from detergents and fertilizers contribute to water pollution. See **Phosphate.**

Photius, *FOH shee uhs* (A.D. 820?-891?), a noted Byzantine scholar and clergyman, became patriarch of Constantinople (now Istanbul, Turkey) in 858. Under the leadership of Photius, a meeting of Eastern patriarchs in 867 challenged papal authority in the Balkans and denounced the pope. This dispute began the great argument between the Greek and Roman Catholic churches that later ended in their separation.

In addition, Photius was known for his digest of the writings of classical Greek authors. The *Myriobiblion* (also called the *Bibliotheca*) is a collection of extracts from, and criticisms and abridgments of, 280 volumes by classical authors. Many originals of these writings ar now lost. Photius was born in Constantinople.

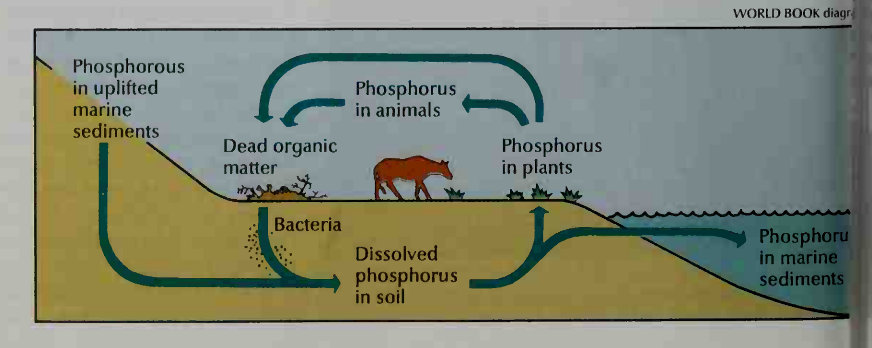
Photochemistry is a branch of chemistry that deals with the chemical reactions that result when the molecules of a substance absorb light. A molecule changes photochemically only if it absorbs light, not if light pass es through it or is reflected.



Light is absorbed in tiny packets of radiant energy called *photons.* The energy of a photon depends on the wavelength of the light. After absorbing a photon, a mo ecule increases in energy and is in an *excited state.* In most cases, the molecule remains in that state only a millionth of a second or less. Sometimes the molecule returns directly to its normal state by releasing the ener gy as light or by losing the energy in collisions with oth er molecules. At other times, the molecule has gained enough energy to undergo unusual chemical reactions while in the excited state. These reactions occur when the molecule absorbs visible or ultraviolet light, which has a short wavelength.

Photochemical reactions are part of many natural processes. In photosynthesis, for example, green plants absorb sunlight. The plants use this light energy to mak food out of carbon dioxide from the air and water from the soil (see **Photosynthesis**). Plants thus convert light energy into the chemical energy of food. Through geological processes, plants may be converted into coal or petroleum. As these fuels are burned, the light energy stored in the plants millions of years before is released.

Many industrial processes also involve photochemical changes. In photography, for example, some of the silver salts in photographic film absorb light when a pic ture is taken. The absorbed light chemically changes these salts into metallic silver. When the film is developed, the metallic silver produces a dark image on the negative.

Much research in photochemistry today involves the development of technological uses of solar energy. Some photochemists are seeking ways to imitate the process of photosynthesis with artificially created mole cules. These chemists hope to convert sunlight into electricity in a more efficient way than is now possible.

Photoengraving and photolithography are processes that use photographic film positives or negatives to make printing plates and cylinders. Photoengraving and photolithography were the leading plate-making processes from the early 1900's until the 1980's. Today, most printers have computerized systems that store *digital* (numeric) files of text and illustrations, and they use lasers to produce images on printing plates or cylinders. Even most printers who still use photoengraving and photolithography use digital files to prepare the film used in the processes.

Photoengraving is a process used to prepare plates for relief printing or plates or cylinders for gravure printing. On plates used for relief printing, the image to be printed is raised above the nonprinting areas. On gravure plates and cylinders, the image consists of shallow depressions in the nonprinting areas. Photolithography is a process used to prepare offset lithographic plates. On offset plates, the image to be printed is level with the areas that do not print. For a discussion of the three printing methods, see **Printing.**

Capturing the image. Most printers use electronic scanners to capture images. A *flat bed scanner* scans *copy* (material to be printed) through a plate of glass on which the copy is laid flat. A *drum scanner* scans copy that has been mounted on a rotating drum. Both types use a light-sensing system that measures reflected light. Devices within the scanner convert the measurements to a digital code. This code is saved as a computer file that can later be used to guide a laser that exposes a sheet of film. To create the range of tones found in a photograph, a scanner converts the image to a *halftone.* A halftone uses dots of varying sizes or spacing to represent the tones in the original.

Scanners can separate color components for color printing. A printing plate prints with only a single color of ink. Printing in color usually requires four plates. Images for color printing are most often separated into

Photoengraving and photolithography convert photographs into *halftones.* An enlargement of a halftone shows that dots of various sizes represent the range of tones in the original.

An offset lithography plat emerges from a plate proce sor. This machine has transferred to the plate's surface image of material that is to b printed. The plate, a flexible sheet of metal, will be wrapped around a printing press cylinder. During printing, both water and ink contact the plate. The image are repel water and attract ink. The nonimage areas accept water and repel ink.

the four colors used to produce a full-color effect in printing. These colors are yellow, *magenta* (a purplish red), *cyan* (a blue), and black. The scanner is programmed to produce the yellow, magenta, and cyan components. A computer uses the color information to compute the black component.

In traditional photoengraving and photolithography, images are put on film photographically. To produce film of a single-color image, a photographer exposes one piece of film. For full-color plates, the photographer makes four exposures—one through each of four color filters—to produce the four color components.

Once film is exposed, whether by scanning or photography, it is developed into a negative. In the negative, the tones are the opposite of those in the original copy.

Transferring the image. Printers use negatives to transfer images to plates used for relief printing and to *negative-working offset plates. Positive-working offset plates* require film or paper positives, which are made by photographing negatives or by printing the negatives on film or light-sensitive paper. Techniques for transfe ring images to gravure plates and cylinders also use fil positives.

The printer fastens the negatives or positives to a sheet of plastic or special paper, creating a *flat.* A devi called a *vacuum printing frame* is used to create an air tight contact between the plate and the flat. In most ca es, light from powerful lamps passes through the trans parent parts of the film, exposing a light-sensitive coating on the plate. What happens next depends upo the type of plate.

Offset plates. There are two main types of offset plates: (1) surface plates and (2) bimetal plates. Both typ can be either negative-working or positive-working. S face plates are used most often. They generally consist of a thin sheet of aluminum covered with a light- or heat-sensitive coating. Aluminum attracts water but re pels ink. The coating repels water but attracts ink. A ne ative-working surface plate has a coating that hardens when exposed to light. A positive-working plate has a

ating that softens when exposed to light or heat. After
ing exposed, the plates are washed in a solution that
moves the unhardened areas of the coating.
Bimetal plates consist of two metals, one on top of the
her. One metal is copper, which has an attraction for
k. The second metal can be chromium, aluminum, or
me other metal with an attraction for water. Bimetal
ates have a coating that hardens when exposed to
ht. After being exposed and washed, the plates are
hed using special chemicals that eat away the uncoat-
areas, revealing the bottom metal layer. Then the lith-
rapher scrubs away the hardened coating.

Plates for relief printing may be metal, rubber, or
stic. Printing with rubber or plastic plates is known as
xography. Metal plates generally are made of zinc,
pper, or magnesium and are coated with a light-sensi-
e substance. They are rarely used for printing. Instead,
ey serve as originals for the production of rubber
ates. After a metal plate is exposed and washed, the
otoengraver places it face down in a machine that
thes one side in acid. The acid etches away the back-
ound of the plate. A plastic mold is then made from
e metal original. A rubber sheet is heated and pressed
o the mold, and is cured to form a plate. Rubber
ates wrap around cylinders on a printing press.
Plastic plates are made of a layer of a *photopolymer,* a
ht-sensitive material that hardens when exposed to
ht, mounted on a metal or plastic base. Plastic plates
e used directly for printing. Like rubber plates, they
ap around press cylinders.

Plates and cylinders for gravure printing. Gravure
esses print with flat copper plates or thick, copper-
ted cylinders. During printing, depressions in the
te, called *cells,* are filled with ink. A thin blade wipes
excess ink from the nonprinting surface. The press
shes paper against the cells, transferring ink to the
per. The cells vary in depth, in area, or in both depth
d area. The shallowest, smallest ones hold the least
, and so they print in the lightest tones.
Gravure plates are exposed through a negative.
avure cylinders are rarely prepared using photo-
aphic processes.

Nonprinting applications. Computer engineers use
otolithography in the manufacture of certain comput-
chips. A light-activated film called a *photoresist* is ap-
ed to a silicon crystal. A *mask,* a sort of stencil, is then
ced over the film. Ultraviolet light shines through the
sk and eats away the film in the areas not covered by
mask. The remaining silicon forms a pattern of cir-
t pathways. Electronics manufacturers also use a pho-
ithographic process to print some computer circuit
ards. Frank J. Romano

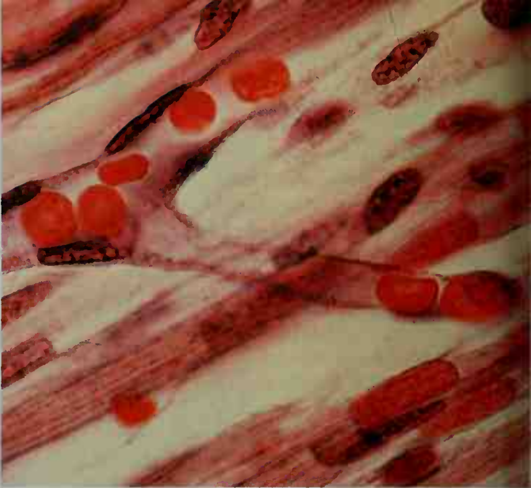
foresters can determine the extent of the damage to the
trees by examining aerial photographs of the area.

Photogrammetrists begin their work by obtaining
photographs of the area or objects to be measured. The
photographs may be taken on the ground or from an
aircraft or spacecraft. Photogrammetrists generally work
with ordinary photographs. But they also use pictures
produced by radar or other *remote sensors,* which
measure features using wavelengths outside the visible
range. *Infrared sensors,* which measure heat, are a type
of remote sensor. Most photographs used in mapmak-
ing are taken from an airplane by a special type of cam-
era. The camera takes photographs of overlapping sec-
tions of the area to be mapped.

To obtain accurate measurements from aerial or other
photographs, a photogrammetrist must correct any dis-
tortion in the pictures. In an aerial photograph, for exam-
ple, a hill appears larger than a valley of equal area.
Such distortion occurs because an airborne camera is
closer to hilltops than to valleys. Photogrammetrists cor-
rect such errors with a device called a *stereoplotter.* This
device uses photographs of an area taken from two lo-
cations to create a three-dimensional image.



Photogrammetry started in 1840, when French physi-
cist and astronomer François Arago demonstrated the
use of photographs in surveying elevations and other
surface features of land. In 1859, Aimé Laussedat, a
colonel in the French Army, announced the first suc-
cessful use of photographs in surveying. Todd I. Blue

Photography is a universal means of communication and a valuable tool in many fields. From family snapshots to pictures taken from spacecraft, photographs record the people and things we see, as well as many subjects beyond our range of vision. Photography is also a major art form. In skillful hands, a camera can transform an ordinary scene into an image of exceptional beauty.

Photography

Photography is the process of making pictures by means of the action of light. Light reflected from an object forms a picture on a light-sensitive device or material. This picture is then chemically or digitally processed into a photograph. The word *photography* comes from Greek words meaning *to write or draw with light.* A photograph is basically a picture drawn with rays of light.

Nearly all photographs are made with cameras. A camera works in much the same way as the human eye. Like the eye, a camera takes in rays of light that are reflected from an object and focuses the rays into an image. But the camera records the image on film or on an electronic storage device, such as a floppy disk or mem ory card. As a result, the image not only can be made permanent but also can be seen by an unlimited number of people.

John Hedgecoe, the contributor of this article, is a professional photographer and the author of numerous books on photography.

Photography enriches our lives in many ways. From photographs, we can learn about people in other parts of the world. Photographs show us scenes from such historic events as the American Civil War (1861-1865) and the first landing on the moon by human beings. Photos also remind us of special people and important events in our own lives. Millions of people throughout the world take pictures of their family, friends, vacation and celebrations.

Special cameras can capture images in places where human beings cannot go—beyond the moon, to the bo tom of the ocean, and inside the human body. Pictures made on film sensitive to heat radiation help physician detect certain forms of cancer and other diseases.

Cameras can also "see" events in a way that the eye cannot. For example, some cameras can record action

rude type of camera was developed by about 1500. However, the first true photograph was not made until 1826. Early photographers needed much equipment and a knowledge of chemistry. Gradually, as a result of the scientific and technical discoveries of the 1800's and 1900's, cameras became more efficient and easier to operate. Today, a person can take a picture simply by aiming the camera and pressing a button. An instant camera can produce a photo in about 15 seconds. Digital cameras, which were introduced in the early 1990's, can produce an image almost instantly. These filmless cameras have a light-sensitive mechanism called a *charge-coupled device* (CCD). The lens focuses light on the CCD, which changes the light into electronic signals. The images can be viewed immediately on cameras equipped with a liquid crystal display (LCD) screen.

Photography can be divided into two general areas—*still photography* and *motion pictures*. This article discusses still photography. For information about motion pictures, see the *World Book* articles on Motion picture and Camcorder.

The photographic process

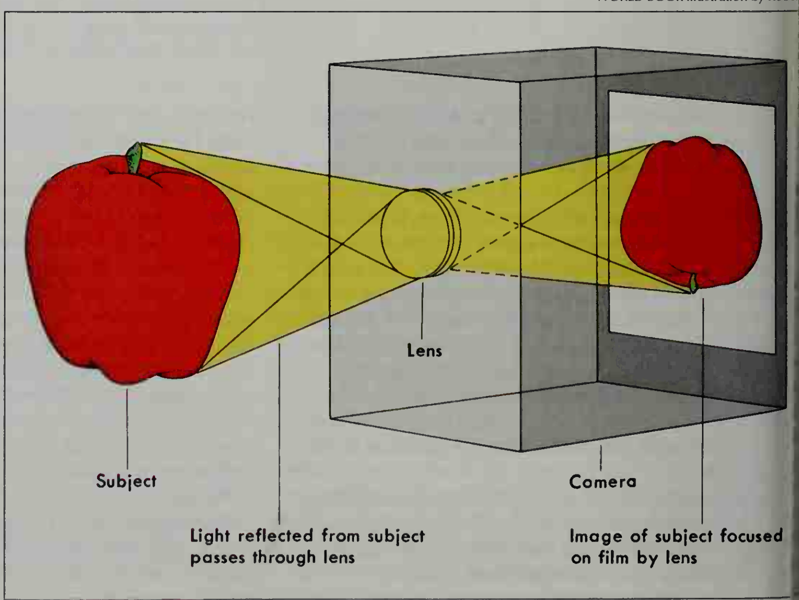
The process of making a photograph begins and ends with light. Rays of light enter a camera and are focused into an image. In traditional photography, light exposes the film in the camera, causing chemical changes on the film's surface. The exposed film is then treated with certain chemicals in a procedure called *developing.* Finally, light is used to make a print by transferring the image from the film to a sheet of special paper.

There are five principal steps in the traditional photographic process: (1) capturing light rays, (2) focusing the image, (3) exposing the film, (4) developing the film, and (5) making a print. This section describes the process of making a black-and-white photograph. The procedures used for making color photographs and instant prints are discussed in the *Developing and printing* section of this article. Pictures taken with a digital camera can be printed using a computer linked to a printer.

Capturing light rays. A camera is basically a box with a small *aperture* (opening) at one end and film at the other end. The inside of a camera must be completely dark so that rays of light reach the film only through the aperture. A device called a *shutter* opens when the camera is being used to take a picture. It remains closed at all other times to keep light away from the film.

In nearly all cameras, the aperture is part of a lens system. The lens system concentrates incoming rays of light on the film. In this way, the lens gathers enough light to expose the film in only a fraction of a second. Without a lens, the exposure might have to last as long as several minutes, and it would not form a sharp image.

When the shutter opens, light from an object passes through the aperture and forms an image of the object on the film. Rays of light from the top of the object go through the aperture and strike the lower part of the film. Light rays from the bottom of the object form the upper part of the image. Thus, the image on the film is upside down.



Focusing the image. In addition to concentrating t incoming rays of light, the camera lens serves to focus them on the film. As the light rays pass through the aperture into the camera, the lens bends them so that they form a sharp image. The sharpness of the image depends on the distance between the object and the lens, and between the lens and the film. Many camera have a focusing mechanism that moves the lens forwa and backward. In other cameras, the lens is fixed. Sucl cameras automatically focus on objects at a certain di tance from the lens. See **Lens.**

Exposing the film. Black-and-white film is a thin sheet of paper or plastic with a coating called an *emu sion.* The emulsion consists of tiny grains of silver salt held together by *gelatin,* a jellylike substance. Silver s are highly sensitive to light and undergo chemical changes when exposed to it. The degree of change in the salts depends on the amount of light that reaches them. A large amount of light causes a greater change than does a small amount.

The light that reaches the film varies in intensity. Lig colored objects reflect much light, and dark colors re flect little or no light. Therefore, the silver salts on the film react differently to different colors. Light from a white or yellow object changes the salts greatly. Light from a gray or tan object changes them only slightly. Black objects do not reflect any light and thus have n effect on the salts. The chemical changes in the silver salts produce a *latent image* on the film. This image c not be seen, but it contains all the details that will appear in the photograph.

Developing the film. After the film has been exposed, it can be removed from the camera. However must then be kept away from light because further ex posure would destroy the latent image. The film is tal to a darkroom or a photographic laboratory. There, it treated with chemical developers that convert the silv

on the emulsion into metallic silver. The image on ilm then becomes visible.

uring development, the silver salts that received h light form a thick deposit of silver and appear on the film. The salts that received little or no light a thin metallic layer or no layer at all. They appear or clear on the film. Thus, the light colors and dark rs of the subjects photographed are reversed on ilm. For example, a piece of coal would appear e on the film, and a snowball would look black. The loped film is called a *negative.* Before further pro- ng, negatives are treated with a chemical solution makes the image on the film permanent.

Making a print is similar to exposing and developing film. Like film, printing paper is coated with a light-sensitive emulsion. Light passes through the negative and exposes the paper, forming a latent image. After development and chemical treatment, the image on the printing paper is visible and permanent.

During exposure, the dark areas of the negative hold back much light. These dark areas show up as light areas on the print. The light and clear areas of the negative let a large amount of light pass through to the printing paper. They appear as dark areas on the print. Thus, the tones of the print reproduce those of the objects photographed.

Nearly anyone can take an ordinary photograph. All you need is a camera, film, light, and a subject. First, you look through the *viewfinder* of the camera to make sure that all of the subject will appear in the picture. Next, you press the *shutter release button* to allow light from the subject to enter the camera and expose the film. Then you use the *film advance,* which moves the film forward through the camera to put unexposed film in position for the next picture.

To take a truly good photograph, you must follow certain principles of photography. You should try to "see" as the camera does—that is, be aware of the elements that compose a picture. You also should know the effects of different types of light on film. Many cameras have controls that adjust the focus of the image and the amount of incoming light. In using such adjustable cameras, you need to know how the lens works and how exposure can be controlled. These aspects of good photography can be grouped as (1) composition, (2) light, (3) focusing, and (4) exposure.

Composition

Composition is the arrangement of elements in a photograph. The elements of composition include line, shape, space, and tone or color. Some guidelines for the use of the various elements may help you create the kind of photograph desired.

Line. There are two principal kinds of lines in photography, *real lines* and *implied lines.* Real lines are physically visible. For example, telephone poles and the edges of buildings form real lines. Real lines help to define space and create *perspective,* the illusion of depth and distance. Implied lines are created by nonphysical factors, such as a person's pointing gesture or gaze.

Both real lines and implied lines can be used to direct a viewer's eye to various parts of a picture. In most effective photographs, the lines draw attention to the main subject. The direction of these lines can also be used to reinforce the mood of a picture. Vertical lines, such as those of a tower or a tall tree, may convey a sense of dignity and grandeur. Horizontal lines tend to suggest peace and stillness, and diagonal ones may emphasiz energy and tension.

Shape is the chief structural element in the compo tion of most photographs. It enables the viewer to im mediately recognize the objects in a picture. Shape al adds interest to composition. The shape of such obje as rocks and seashells is interesting in itself. A combi tion of different shapes provides variety. For example outdoor scene can be made more interesting by contrasting the jagged shape of a fence with the soft cur of hills and clouds.

Space is the area between and surrounding the ob jects in a photograph. Space can be used to draw atte tion to the main subject and to isolate details in the pi ture. However, large amounts of space tend to detrac from a picture's interest. A general principle for the u of space is that it should not occupy more than a thir the photo.

Tone or color adds depth to the composition of a photograph. Without this element, the shapes and spaces in a picture would appear flat. In black-and-wl photography, the colors of objects are translated into tones of black, gray, and white. These tones help esta lish the mood of a picture. If light tones dominate the photo, the mood may seem happy and playful. A pict with many dark tones may convey a sense of sadness mystery.

Color, like tone, carries an emotional message. In a color photograph, such bright colors as red and orar create an impression of action and energy. Blue, gre and other softer colors are more restful to the eye an may suggest a feeling of peace. According to many p fessional photographers, a color picture should have one dominant color and a balance between bright c ors and softer shades.

Light

There are two basic types of light in photography, ural light and *artificial light.* Natural light, which is als called *available light* or *existing light,* is normally pre in outdoor and indoor locations. Such light comes

efly from the sun and electric lights. Artificial light is oduced by various types of lighting equipment, such photoflood lamps and electronic flash devices. Lighting equipment is discussed in the *Photographic equipnt* section.

Natural light and artificial light have certain charactercs that greatly affect the quality of photographs. ese characteristics include (1) intensity, (2) color, and direction.

ntensity is the quantity or brightness of light. Phoraphers measure the intensity of light to determine *lighting ratio* of a scene. The lighting ratio is the difence in intensity between the areas that receive the st light and those that receive the least. On a sunny or in a room with bright lights, the lighting ratio may high. On a cloudy day or in dim indoor light, the ratio robably low.

The lighting ratio affects the degree of contrast in a otograph. A high lighting ratio may produce sharp ages with deep shadows and bright highlights. A low o creates softer images with a wide range of medium es. Thus, a high lighting ratio can create a sense of ma and tension in a picture. A low lighting ratio makes portraits and still-lifes look more natural.

Most lighting ratios can be used with black-and-white film. In taking color photographs, however, a high lighting ratio may make some colors appear either faint or excessively dark.

Color. The color of light varies according to its source, though most of these variations are invisible to the human eye. For example, ordinary light bulbs produce reddish light, and fluorescent light is basically blue-green. The color of sunlight changes during the day. It tends to be blue in the morning, white at about noon, and pink just before sunset.

Variations in the color of light make little difference in a black-and-white photograph. In color pictures, however, they produce a wide variety of effects. To control these effects, you can use color filters on your camera, or you can use color film that is designed for different types of indoor and outdoor lighting. Such accessories are discussed in the *Photographic equipment* section of this article.

Direction refers to the direction from which light strikes a subject. Light may reach a subject from the front, the back, the side, or the top. Light may also strike

Outdoor lighting

The sun is the main source of light in most photos taken outdoors. When the subject faces the sun, sunlight illuminates the face clearly but may cause the person to squint. Sunlight shining on one side of the subject casts shadows on the other side. These shadows can be filled in with light from an electronic flash device or some other source.

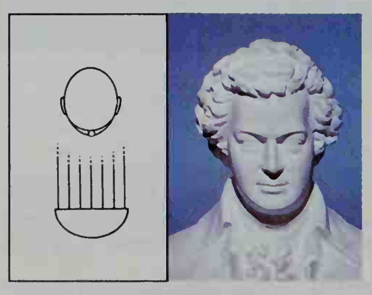
a subject from several directions at once. The direction greatly affects how the subject looks in the picture.

Front lighting comes from a source near or behind the camera. This type of lighting shows surface details clearly. However, it should be avoided for pictures of people because the light makes them squint and casts harsh shadows under their features.

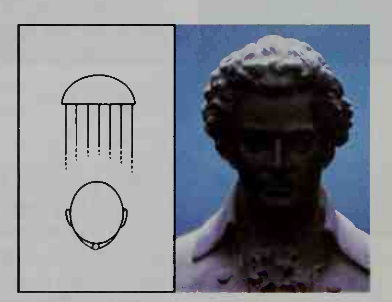
Back lighting comes from a source behind the subject. Light from this direction casts a shadow across the front of the subject. To fill in the shadow, additional light from an electronic flash can be used. This technique is called *flash fill-in.* If the back lighting is extremely bright, the picture may show only the outline of the subject. Back lighting can be deliberately used in this way to create silhouettes.

Side lighting shines on one side of the subject. Shadows fall on the side opposite the source of the light. Flash fill-in can be used to lighten these shadowed areas. Side lighting does not show surface detail as clea as front lighting does, but it creates a strong impressi of depth and shape.



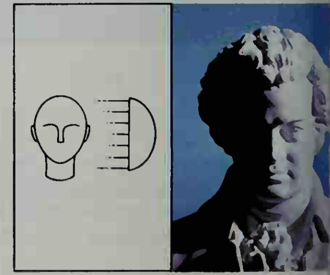
Top lighting comes from a source directly above th subject. It is used most frequently in situations where other types of lighting would cause a glare or reflecti in a picture. For example, top lighting may be used to photograph fish in an aquarium or objects in a displa case or behind a window because the light will not b reflected by the glass.

Focusing

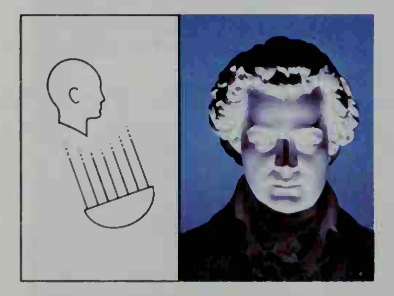


Focusing controls the sharpness of the image in a photograph. The degree of sharpness is determined b (1) the distance between the camera lens and the subj and (2) the distance between the lens and the film insi

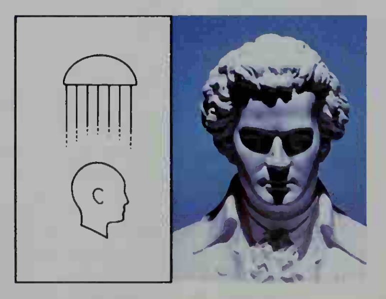
Indoor lighting



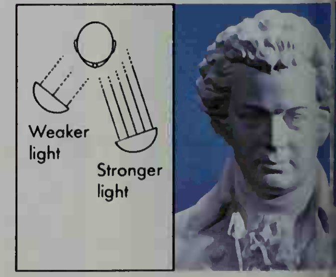
WORLD BOOK diagrams and pl



Front lighting comes from a source near the camera. It highlights the subject's face, reducing some surface detail.



Back lighting comes from a source behind the subject. It throws a shadow over the entire front of the subject.



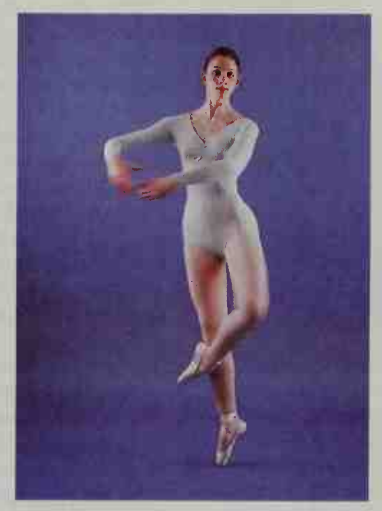
Side lighting shines on one side of th subject. It casts shadows on the side o posite the source of light.

Bottom lighting comes from below the subject. It produces harsh highlights that distort the subject's appearance.

Top lighting comes from directly above the subject. It creates an extreme contrast between light and shadow.

Multiple lighting can be used to ligh the shadows produced by individual sources of light.

ing shutter speed "stop" action



Shutter speed is the amount of time the shutter remains open during exposure. At the slow shutter speeds of 1 second or $\frac{1}{60}$ of a second, all or part of a moving dancer looks blurred. At a fast setting, such as $\frac{1}{500}$ of a second, the shutter is open so briefly that the dancer's movement appears "stopped."

camera. To form a sharp image of a subject that is se to the camera, the lens must be relatively far from film. For subjects far from the camera, the lens must close to the film. See **Lens**.

n nonadjustable cameras—that is, cameras without a ntrol to adjust the focus—focusing depends on taking tures at a certain distance from the subject. Most h cameras are designed to focus on subjects more n 6 feet (1.8 meters) away. If the subject is closer than et, the picture will be blurred.

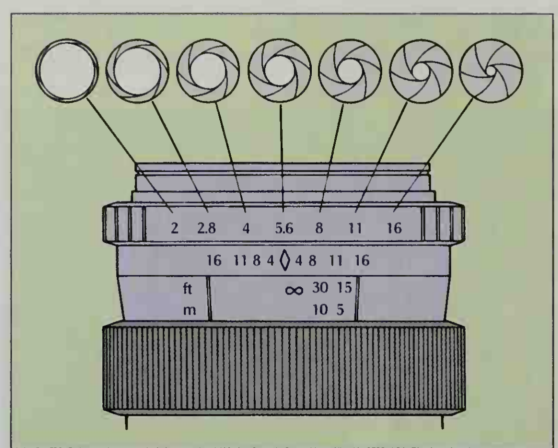
Adjustable cameras have a focusing mechanism that anges the distance between the lens and the film. ıny of these cameras contain a built-in *viewing screen* t provides an image of the subject while the photog- her focuses. Various devices on the viewing screen licate the proper focus. In some cameras, the viewing een shows two identical images or one image split ɔ two halves. To focus, the photographer turns the fo- ;ing control until the double image becomes one ırp image or until the two halves come together. In ıer cameras, tiny dots appear on the screen until the ıge has been focused.

Exposure

Exposure is the total amount of light that reaches the ı in a camera. Exposure affects the quality of a photo- .ph more than any other factor. If too much light en- s the camera, the film will be *overexposed,* and the ture will be too bright. If there is insufficient light, the ı will be *underexposed,* resulting in a dark, uninter- ing picture.

n nonadjustable cameras, the exposure is set auto- tically. Most adjustable cameras have controls that ulate the incoming light. To set the exposure on such ımera, the photographer adjusts the settings on se controls.

Controlling exposure. Adjustable cameras have two controls that regulate exposure. One of these controls changes the speed of the shutter, and the other changes the size of the aperture.



Shutter speed is the amount of time the shutter remains open to let light expose the film. A slow shutter speed lets in a large amount of light, and a fast shutter speed admits only a little.

Many adjustable cameras have a range of shutter speeds that vary from 1 second or longer to $\frac{1}{1,000}$ of a second or faster. These speeds are represented by whole numbers on the standard scale of shutter speeds. The number 500 on the scale stands for $\frac{1}{500}$ of a second, 250 means $\frac{1}{250}$ of a second, and so on. Each number on the scale represents twice the speed of the preceding number or half the speed of the next number. At a setting of 250, for example, the shutter works twice as fast as at a setting of 125 and half as fast as at a setting of 500.

Fast shutter speeds enable photographers to take sharp pictures of moving subjects. Any movement of the subject while the shutter remains open will be recorded as a blur. At a setting of $\frac{1}{1,000}$ of a second or faster, the shutter is open for such a short time that even the motion of a speeding race car appears to be "stopped."

Aperture size is changed by a device called a *diaphragm,* which consists of a circle of overlapping leaves. The diaphragm expands to make the aperture larger and contracts to make it smaller. A large aperture admits more light than a small one.

The various sizes of an aperture are called *f-stops* or *f-numbers.* On most adjustable cameras, the f-stops range from 1.4 or 1.8 to 22 or 32 and include 2, 2.8, 4, 5.6, 8, 11, and 16. The smaller the number, the larger the size of the aperture. Like the shutter speeds, each f-stop lets in either twice as much light as the preceding setting or half as much light as the next higher setting. For exam-

ple, if you *open up* the setting from f/11 to f/8, the aperture admits twice as much light into the camera. If you *stop down* the setting from f/11 to f/16, the aperture lets half as much light into the camera.

Changes in the size of the aperture affect the overall sharpness of the picture. As the aperture becomes smaller, the area of sharpness in front of and behind the subject becomes larger. This area of sharpness is called *depth of field.* It extends from the nearest part of the subject area in focus to the farthest part in focus. A small aperture, such as f/11 or f/16, creates great depth of field. As you open up the aperture, the area in focus becomes shallower. At f/4 or f/2, the subject will be in focus, but objects in the foreground and background may be blurred.

Setting the exposure. The proper exposure for a picture depends chiefly on (1) the lighting, (2) the subject, and (3) the desired depth of field. Each of these factors may require an adjustment in shutter speed or aperture size. You must choose a combination of settings that will meet all the requirements.

The amount of light in a scene affects both shutter speed and aperture size. On a cloudy day, you shoulc reduce the shutter speed and increase the f-stop. On sunny day, you should use settings for a fast shutter a a small aperture. Certain types of artificial lighting hav special requirements for exposure.

The type of subject to be photographed may requi an adjustment in the shutter speed, and depth of fielc may determine the aperture size. If the subject is mov ing, you must increase the shutter speed to prevent blurring. If you want a large area of the picture to be i sharp focus, you should choose a small aperture to p vide greater depth of field.

If you adjust either the shutter speed or the apertu size, you must also adjust the other. A fast shutter spe stops the action, but it also reduces the amount of lig reaching the film. To make up for this reduction in lig you should increase the f-stop. Similarly, a small aper ture increases depth of field but reduces the amount incoming light. Therefore, you should change to a slc er shutter speed.

Suppose you want to photograph some squirrels o sunny day. A suitable exposure might be a shutter sp of $\frac{1}{60}$ and an aperture of f/11. If the squirrels are movi you might increase the shutter speed to $\frac{1}{125}$. This spee is twice as fast as $\frac{1}{60}$ and so half as much light will rea the film. You should make the aperture twice as large setting it at f/8.

You may want the photograph to include some acorns on the ground in front of the squirrels, and al the trees in the background. You can increase depth field by reducing the size of the aperture. At a setting f/16, the film will receive half as much light as it did a f/11. You should also change the shutter to the next slowest speed, so that the film will be exposed for tw as long. At a slow shutter speed, however, blurring fr movement of the squirrels or the camera may occur. better option in this situation might be to retain the faster shutter speed and use a faster speed of film. Fo information on film speed, see the *Film* section of thi article.

Controlling depth of field

Depth of field is the area of sharpness in front of and behind the subject of a photo. The size of this area can be controlled by adjusting the aperture setting on a camera. A wide aperture produces shallow depth of field, and a small one creates great depth of field.

At f/2, depth of field extends only a short distance from a subject in focus. If the objects in front are sharp, those in back are blurred.

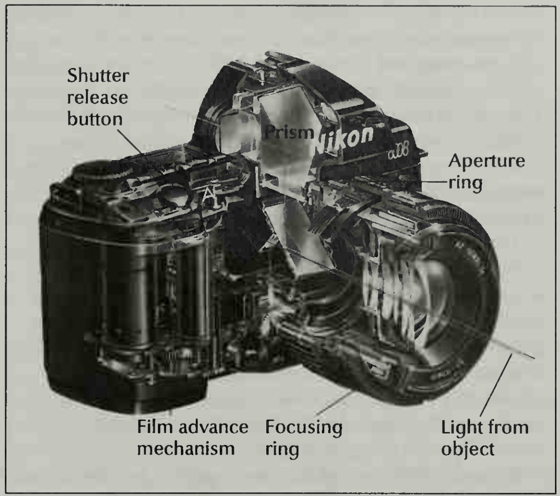
Cameras

Nearly all cameras have the same basic design, which cludes an aperture, a shutter, a viewfinder, and a film vance. However, cameras vary widely in such features adjustability and the type of film used.

The simplest cameras, called *fixed-focus cameras,* ve a nonadjustable lens and only one or two shutter eeds. Most of these cameras use 35-millimeter or adnced photo system (APS) film. APS film has a width of millimeters. A cassette of APS film is smaller and hter in weight than a 35-millimeter film cassette. APS meras are, in general, smaller and lighter than 35-milneter cameras.

Professional cameras, including *view cameras* and *udio cameras,* have many adjustable parts. Most such meras use large sheets of film. *Digital cameras* do not e film. Instead, they store images as electronic inforation that can be used on a computer. For more inforation on view cameras, studio cameras, and digital meras, see **Camera.**

One common classification for cameras is based on e viewing system. The principal types of cameras sed on viewing systems are (1) direct vision, (2) singlens reflex, and (3) twin-lens reflex.



Direct vision cameras have a viewing system that is parate from the lens. The category includes *range der* and *point and shoot* cameras. Many direct vision meras are lightweight and relatively inexpensive. ost use 35-millimeter film.

On most direct vision cameras, the viewfinder is a nall window near the lens. On a range finder camera, angled mirror behind the lens reflects a second ime of the subject into the viewfinder. To focus, a pern looks through the viewfinder and adjusts the focus- mechanism until the two images come together. The cused image in the viewfinder differs slightly from the age on the film. This difference is called *parallax error.* help correct for parallax error, the viewfinder has es that frame the subject area "seen" by the lens.

Point and shoot cameras include electronic devices at automatically adjust the focus and set the light expore. Some point and shoot cameras use APS film.

Single-lens reflex cameras enable a photographer look at a subject directly through the lens. A mirror echanism between the lens and the film reflects the age onto a viewing screen. When the shutter release tton is pressed, the mirror rises out of the way so that light exposes the film. Thus, the photographer sees image almost exactly as it is recorded on the film, d parallax error is avoided.

Single-lens reflex cameras are heavier and more exnsive than most direct vision models. Most use 35llimeter film. Others use APS film. Single-lens reflex meras can utilize a variety of interchangeable lenses. eir standard lens can be replaced by lenses that ange the size and depth relationships of objects in a ene. Such lenses include *wide-angle lenses, telephoto ses, macro lenses,* and *zoom lenses.*

Nikon, Inc.

A single-lens reflex camera, or *SLR camera,* lets a photographer view subjects directly through the lens. Most SLR models have controls for focusing, aperture size, and shutter speed.

A wide-angle lens provides a wider view of a scene than a standard lens does. It is used for large scenes and in locations where the photographer cannot move back far enough to photograph the entire scene. A telephoto lens makes objects appear larger and closer. It enables photographers to take detailed pictures of distant subjects. A macro lens, which is used in extreme close-up photography, focuses on subjects from a short distance. A zoom lens combines many features of standard, wide-angle, and telephoto lenses.

Twin-lens reflex cameras have their viewing lens directly above the picture-taking lens. The image in the viewing lens is reflected onto a screen at the top of the camera. A person holds the camera at waist- or chest-level and looks down at the viewing screen.

The viewing screen of a twin-lens reflex camera is much larger and clearer than those of eye-level cameras. Most twin-lens reflex models use film that produces negatives measuring $2\frac{1}{4}$ by $2\frac{1}{4}$ inches (5.7 by 5.7 centimeters). However, these cameras are subject to parallax error and are heavier than the majority of single-lens reflex cameras. Also, most twin-lens reflex cameras do not have interchangeable lenses.

Film

A majority of the cameras used by amateur and professional photographers require 35-millimeter film. The image captured on this film has an *aspect ratio* of 2 to 3. The aspect ratio is a comparison of the horizontal or vertical length of the image to its other dimension. An APS camera captures images that can be printed using any of three different aspect ratios. In addition to the emulsion that captures the image, APS film includes a magnetic coating. At the time a picture is taken, the photographer stores information in this coating directing a film laboratory to produce the print in a specific aspect ratio. Prints can be made later using a different format. *Classic format* produces prints with the same ratio as those pro-

duced by 35-millimeter film; *H format,* or *HDTV format,* has an aspect ratio of 9 to 16; and *panoramic format* has an aspect ratio of 1 to 3. Some APS cameras enable the photographer to magnetically store such information as a title to be added to the photograph or the number of prints to be produced from each individual image.

APS film offers a greater number of exposures than 35-millimeter film. The 35-millimeter standard offers 12, 24, or 36 exposures per roll. APS film offers 15, 25, or 40.

There are three main kinds of photographic film, based on the type of pictures produced. Black-and-white prints are made from *black-and-white negative film,* color prints from *color negative film,* and color slides from *color reversal film.* Film of each type varies in a number of characteristics that affect the overall quality of photographs. The most important of these characteristics include (1) speed, (2) graininess, (3) color sensitivity, and (4) color balance.

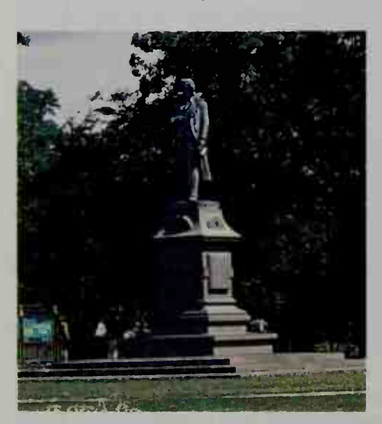
Speed is the amount of time required for film to react to light. A film's speed determines how much exposure is needed to record an image of the subject. A fast film reacts quickly to light and needs little exposure. It is useful for scenes that have dim light or involve fast action. A medium-speed film requires moderate exposure and is suitable for average conditions of light and movement. A slow film needs much exposure and should be used for stationary subjects in a brightly lighted scene.

The principal systems of measuring film speed are the *DIN system,* used chiefly in Western Europe, and the international *ASA* and *ISO* systems. ASA stands for the American Standards Association, and ISO stands for the International Organization for Standardization. The higher the ASA or ISO number, the faster the film. Films that have numbers of 200 or higher are generally considered fast. Medium-speed films have numbers ranging from 80 to 125, and slow films are numbered lower than 80.

Graininess is the speckled or hazy appearance of some photographs. It is caused by clumps of silver grains on the film. The degree of graininess depends on the speed of the film. A fast film is more sensitive to light than other films are because its emulsion contains larger grains of silver salts. The fastest films produce the grainiest pictures. Medium-speed films and slow films produce little or no graininess in standard-sized prints though some graininess may appear in enlargements.

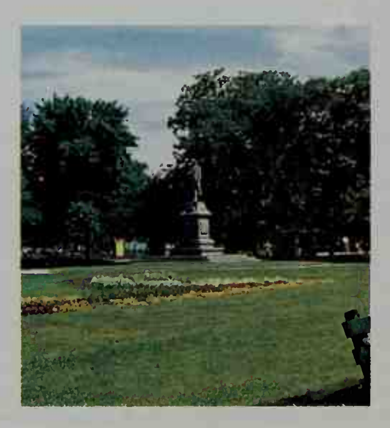
Color sensitivity refers to a black-and-white film's ability to record differences in color. On the basis of c or sensitivity, black-and-white films are classified into several types, including *panchromatic film* and *orthochromatic film.* Panchromatic film, the most widely use type, is sensitive to all visible colors. Orthochromatic film records all colors except red. It is used chiefly by commercial artists to copy designs that have few color

Color balance applies only to color film. Such film i sensitive to all colors, including those of different kind of light. The human eye sees light from most sources a white. But color film records light from light bulbs as reddish, light from fluorescent bulbs as blue-green, an daylight as slightly blue. Variations in the emulsions of different types of color film make the film less sensitive to certain colors. These variations balance the color of light recorded on the film so colors in the photograph appear natural. Most color film is balanced either for daylight or for specific types of artificial light.



Lighting equipment

Lighting equipment can be divided into two basic ca egories according to function. *Exposure meters,* the fir category, measure the light available for photography. *Artificial lighting devices,* the second category, provid any additional light needed to take a picture.



Exposure meters, also called *light meters,* help determine the correct exposure. Exposure meters are hel in the hand or are built into a camera. Handheld meter record the light in a scene and indicate the camera settings for the proper exposure. Built-in meters measure the light that strikes the lens of the camera. Light readings appear on a scale on the viewing screen. Some cameras with exposure meters automatically adjust th shutter speed and aperture size to the amount of light

Some types of camera lenses The standard lens on many cameras can be replaced by specialized lenses, such as a *wide-angle lens* or a *telephoto lens.* A wide-angle lens provides a wider view of a scene but makes objects appear smaller and farther away. A telephoto lens makes the subject seem larger and closer.

ailable. Exposure meters are classified according to e way they measure light. They include (1) reflected ıht meters and (2) incident light meters. Many hand-ld instruments can be used as both types of meters. ost built-in meters are reflected light meters.

Reflected light meters measure the light reflected om a scene toward the camera. Various areas in the ene reflect different amounts of light. Most built-in eters show the average amount of light reflected from the areas. To measure reflected light with a handheld eter, the meter should be aimed at the main part of e scene. If there are strong contrasts in light and shad-v, separate readings of the brightest and darkest areas ıould be taken and then averaged.

Incident light meters measure the light falling on a ıbject. When measuring this kind of light, the photog-pher should stand near the subject and point the me-r toward the spot where the photo will be taken.

Artificial lighting devices. The most widely used ıurce of artificial lighting is the electronic flash, which ovides a short burst of light. Many professional pho-graphers use *photoflood lamps*—lighting devices that ın provide continuous light for several hours.

Most cameras have a built-in device called a *flash syn-ıronizer.* A flash synchronizer coordinates the flash sys-m with the shutter, so that the greatest brightness of e flash occurs at the instant the shutter reaches its full oening. On many cameras, the flash synchronizer orks for electronic flash at a setting of *X.*

Electronic flash units operate on batteries or on elec-ic current from an outlet. They contain an *ionized* (electrically charged) gas inside a sealed tube. The gas emits a burst of bright light when an electric current is passed through it. Electronic flash units can fire thousands of flashes. Electronic flash equipment ranges from small flash units that fit onto the top of a camera to large studio units. Some flash devices are small enough to be built into cameras. Camera-top flash units are mounted onto a flat piece of metal called a *hot shoe.* The hot shoe contains electrical contacts for the flash unit so that it can be triggered by the flash synchronizer.

Filters

A photographic filter is a disk of colored, plasticlike gelatin or colored glass in a holder. The holder fits over the lens of specific types of cameras. Filters screen out haze and glare or increase the contrast among tones in a picture. Nearly all filters hold back some light from the film. Therefore, when using a filter on most cameras, you must increase the exposure by the *filter factor* listed in the instructions provided with the film.

The most widely used filters include *ultraviolet filters, polarizing filters,* and *color filters.* An ultraviolet filter reduces haze. It is useful for photographing distant subjects and for taking pictures at high altitudes. A polarizing filter makes colors more vivid and screens out glare from shiny surfaces, such as water and glass. A color filter increases contrast in black-and-white photographs. It lets light of its own color pass through the lens to the film but holds back certain other colors. As a result, objects that are the same color as the filter appear light in the picture, and the blocked colors are dark. Suppose you use a red filter when taking a black-and-white photograph of an apple tree. The apples will look light gray, and the leaves and the sky will be dark gray or black.

Tripods

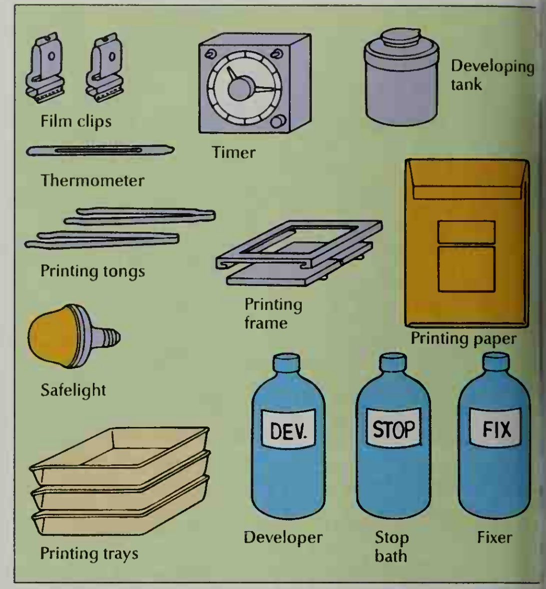
Movement of a camera during a long exposure may blur the picture. If the exposure time is more than $\frac{1}{30}$ second, a photographer should use a camera support. The most common type of support is a three-legged device called a tripod.

The steadiest tripods are built for studio use or to support heavy cameras and lenses. These tripods may be too heavy to be carried around by a photographer doing field work. Lighter, more portable tripods with retractable legs are used by most serious photographers. On most tripods, three legs support a center column. The column can move up and down to adjust the height without adjusting the length of the tripod's legs. The camera is mounted on the tripod's *head,* at the top of the column. Handles and knobs on the head enable the photographer to change the angle of the camera shot by *panning* left and right and *tilting* up and down.

Developing and printing

After the picture has been taken, the latent image on e film cannot be seen. The image becomes visible rough the process of developing the film into a nega-/e. The negative shows the reverse of the subject's ght and dark areas. During printing, the image on the film is transferred onto paper, and the original colors or tones of the subject are restored.

Most amateur photographers have their film processed in commercial laboratories. Some photographers, however, choose to develop and print their own pic-



tures. By processing and printing the film themselves, they can change the size, composition, contrast, and other features of the photographs.

Black-and-white film and color film are developed and printed in much the same way. Most types of film are removed from the camera and processed in a darkroom or a photographic laboratory. Instant film contains all of the materials needed to create a positive print. It produces photographs directly from the camera.

It is more complicated and expensive to process color film than to process black-and-white film. The processing of color film requires extra steps and some additional materials. Many fewer amateur photographers develop color film than develop black-and-white film.

APS film is intended to be developed only in a film laboratory. The laboratory returns the negatives stored in the original film cassette. For a laboratory to produce prints as intended by the photographer, it must have equipment that can read the information stored on the film magnetically.

Developing black-and-white film requires two or more chemical solutions, several pieces of equipment, and running water. The chemical solutions should be stored in amber-colored bottles made of polyethylene plastic. Such bottles are highly resistant to chemicals and keep light from harming the solutions. Each bottle
